Table of Contents

Section 2
Tools and Technologies

This section presents an extensive coverage of various tools and technologies available in the field of Curriculum Design and Classroom Management that practitioners and academicians alike can utilize to develop different techniques. These chapters enlighten readers about fundamental research on the many tools facilitating the burgeoning field of Curriculum Design and Classroom Management. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of Curriculum Design and Classroom Management. With 13 chapters, this section offers a broad treatment of some of the many tools and technologies within the Curriculum Design and Classroom Management field.

Section 3
Frameworks and Methodologies

This section provides in-depth coverage of conceptual architecture frameworks to provide the reader with a comprehensive understanding of the emerging developments within the field of Curriculum Design and Classroom Management. Research fundamentals imperative to the understanding of developmental processes within Curriculum Design and Classroom Management are offered. From broad examinations to specific discussions on methodology, the research found within this section spans the discipline while offering detailed, specific discussions. From basic designs to abstract development, these chapters serve to expand the reaches of development and design technologies within the Curriculum Design and Classroom Management community. This section includes 16 contributions from researchers throughout the world on the topic of Curriculum Design and Classroom Management.

Section 4
Cases and Applications

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective Curriculum Design and Classroom Management programs and processes. This section includes 20 chapters that discuss Curriculum Design and Classroom Management in a variety of settings. Contributions included in this section provide excellent coverage of today's IT community and how research into Curriculum Design and Classroom Management is impacting the social fabric of our present-day global village.

Section 6
Emerging Trends

This section highlights research potential within the field of Curriculum Design and Classroom Management while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are chapters that set the stage for future research directions and topical suggestions for continued debate, centering on the new venues and forums for discussion. A pair of chapters on the usability and effectiveness research makes up the middle of the section of the final 10 chapters, and the book concludes with a look ahead into the future of the Curriculum Design and Classroom Management field, with "Trends of Blended Learning in K-12 Schools: Challenges and Possibilities." In all, this text will serve as a vital resource to practitioners and academics interested in the best practices and applications of the burgeoning field of Curriculum Design and Classroom Management.

Preface

The constantly changing landscape of Curriculum Design and Classroom Management makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Information Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within Curriculum Design and Classroom Management by providing both broad and detailed perspectives on cutting-edge theories and developments. This reference is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as provide insight into emerging trends and future opportunities within the discipline.

Curriculum Design and Classroom Management: Concepts, Methodologies, Tools and Applications is organized into six distinct sections that provide comprehensive coverage of important topics. The sections are: (1) Fundamental Concepts and Theories, (2) Tools and Technologies, (3) Frameworks and Methodologies, (4) Cases and Applications, (5) Issues and Challenges, and (6) Emerging Trends. The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of Curriculum Design and Classroom Management. Introducing the book is "Literature Review in Conceptions and Approaches to Teaching using Blended Learning," a great foundation laying the groundwork for the basic concepts and theories that will be discussed throughout the rest of the book. Another chapter of note in Section 1 is titled "Flipping STEM Learning: Impact on Students' Process of Learning and Faculty Instructional Activities," which discusses the novel techniques of pathway analytics to assist Curriculum Design and Classroom Management policies and tactics. Section 1 concludes, and leads into the following portion of the book with a nice segue chapter, "Technology-Enhanced Learning: Towards Providing Supports for PhD Students and Researchers in Higher Education." Where Section 1 leaves off with fundamental concepts, Section 2 discusses tools and technologies in place for Curriculum Design and Classroom Management.

Section 2, "Tools and Technologies," presents extensive coverage of the various tools and technologies used in the implementation of Curriculum Design and Classroom Management. Section 2 begins where Section 1 left off, though this section describes more concrete tools at place in the modeling, planning, and applications of Curriculum Design and Classroom Management. The first chapter, "A Quest about eQuest and Blended Learning in Teacher Education: An Indian Study," lays a framework for the types of works that can be found in this section, a perfect resource for practitioners looking for the types of technologies currently in practice in Curriculum Design and Classroom Management. Section 2 is full of excellent chapters like this one, including such titles as "A Blended Course to Teach Graphical Programming Using LabVIEW," "Fantasy Workshop: Active Use of a Learning Management System

(LMS) as an Approach to Blended Learning," and "Increasing Research Students' Engagement through Virtual Communities," to name a few. Where Section 2 described specific tools and technologies at the disposal of practitioners, Section 3 describes frameworks and methodologies within the field.

Section 3, "Frameworks and Methodologies," presents in-depth coverage of the conceptual design and architecture of Curriculum Design and Classroom Management. Opening the section is "Blended Course Design: Where's the Pedagogy?" This section is vital for developers and practitioners who want to measure and track the progress of Curriculum Design and Classroom Management through the multiple lens of parametric design. Through case studies, this section lays excellent groundwork for later sections that will get into present and future applications for Curriculum Design and Classroom Management, including, of note: "Blended Learning for Learners in SMEs" and "Blending in the Humanities: Course Model and Assessment Results." The section concludes with another excellent work on sequence design, titled "Prioritization of Design Requirements for Quality Engineering Education."

Section 4, "Cases and Applications," describes how the broad range of Curriculum Design and Classroom Management efforts has been utilized and offers insight on and important lessons for their applications and impact. Section 4 includes the widest range of topics because it describes case studies, research, architectures, theory, analysis, and guides for implementation. The first chapter in the section is titled "How Do They Fare? Learning Achievement and Satisfaction with Blended Learning for Traditional-Age Undergraduates at Moderately Selective Colleges" The breadth of topics covered in the chapter is also reflected in the diversity of its authors, from countries all over the globe. Section 4 concludes with an excellent view of a case study in a new program, "M-Learning in the Middle East: The Case of Bahrain."

Section 5, "Issues and Challenges," presents coverage of academic and research perspectives on Curriculum Design and Classroom Management tools and applications. The section begins with "Using a Task-Based Approach for Supporting a Blended Learning Model for English as a Foreign Language." The section concludes with "Artful Learning: Holistic Curriculum Development for Mind, Body, Heart, and Spirit," a great transitional chapter between Sections 5 and 6 because it examines an important trend going into the future of the field. The last chapter manages to show a theoretical look into future and potential technologies, a topic covered in more detail in Section 6.

Section 6, "Emerging Trends," highlights areas for future research within the field of Curriculum Design and Classroom Management, opening with "Preparing to Teach with Flipped Classroom in Teacher Preparation Programs." Section 6 contains chapters that look at what might happen in the coming years that can extend the already staggering amount of applications for Curriculum Design and Classroom Management. Other chapters of note include "E-Learning: A Means to Increase Learner Involvement in Research" and "To Flip Or Not To Flip? That's Not the Question: Exploring Flipped Instruction in Technology Supported Language Learning Environments." The final chapter of the book looks at an emerging field within Curriculum Design and Classroom Management, in the excellent contribution, "Trends of Blended Learning in K-12 Schools: Challenges and Possibilities."

Although the primary organization of the contents in this multi-volume work is based on its six sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume.

As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Curriculum Design and Classroom Management: Concepts, Methodologies, Tools and Applications*, provides researchers, administrators, and all audiences with a complete understanding of the development of applications and concepts in Curriculum Design and Classroom Management. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of Curriculum Design and Classroom Management in countries around the world, *Curriculum Design and Classroom Management: Concepts, Methodologies, Tools and Applications* addresses the demand for a resource that encompasses the most pertinent research in technologies being employed to globally bolster the knowledge and applications of Curriculum Design and Classroom Management.

Section 1

Fundamental Concepts and Theories

This section serves as a foundation for this exhaustive reference tool by addressing underlying principles essential to the understanding of Curriculum Design and Classroom Management. Chapters found within these pages provide an excellent framework in which to position Curriculum Design and Classroom Management within the field of information science and technology. Insight regarding the critical incorporation of global measures into Curriculum Design and Classroom Management is addressed, while crucial stumbling blocks of this field are explored. With 14 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring the Curriculum Design and Classroom Management discipline.

Chapter 1
Literature Review in Conceptions and Approaches to Teaching using Blended Learning

Vicki Caravias
Swinburne University of Technology, Australia

ABSTRACT

This paper presents a critical review and synthesis of research literature in higher education exploring teachers' conceptions of blended learning and their approaches to both design and teaching. Definitions of blended learning and conceptual frameworks are considered first. Attention is given to Picciano's Blending with Purpose Multimodal framework. This paper builds upon previous research on blended learning and conceptual framework by Picciano (A. Picciano, 2009) by exploring how objectives from Picciano's framework affect teachers' approaches to both design and teaching in face-to-face and online settings. Research results suggest that teachers use multiple approaches including face-to-face methods and online technologies that address the learning needs of a variety of students from different generations, personality types and learning styles.

1. INTRODUCTION

Over the past two decades the integration of Internet and Information and Communication Technologies (ICT) have enhanced knowledge and performance in many university courses (S. Jones, Johnson-Yale, Millermaier, & Pérez, 2008). Within higher education, Kanuka and Kelland (2008) reflect that:

Higher education literature on e-learning technology is replete with research that tinkers with, and then tests the effects if, instrumental practices. The ultimate aim is to determine once and for all, what works and what does not – passing by the questions of why (p.61).

During this time universities have incorporated learning management systems, such as Blackboard and Moodle, into their teaching practices (R. A.

DOI: 10.4018/978-1-4666-8246-7.ch001

Ellis, Goodyear, Prosser, & O'Hara, 2006; R. A. Ellis, Steed, & Applebee, 2006) to support teachers in delivering material to students. Learning Management Systems (LMS) provide the opportunity to deliver blended learning approaches that combine a mix of ICT with various learning resources and delivery methods. Coates et al. (2005) outline several key features of LMSs:

1. Asynchronous and synchronous communication between teacher-student and student-student (discussion boards, emails, live chats);
2. Content development and delivery (lecture notes, readings, practical activities);
3. Formative and summative assessment (submission of assignments, quizzes, collaborative work feedback, grades);
4. Class and user management (enrolling students, displaying timetable) (p. 20-21).

Coates, James and Baldwin (2005) found that LMS studies focused on the economic and technical issues of LMS usage (p. 26). They are also critical of the "textual nature" of LMSs (p. 27). Similarly, Prendergast (2004) argues:

Too often considerations about information technology have become the dominant factors in many strategies adopted by academic institutions. This has resulted in a rich information technological environment that fails to capture, motivate or retain learners (p.2).

Brabazon (2002) supports this view, by stating that:

Teachers and teaching are being challenged and undermined through the Internet. Learning is not technologically dependent. It is reliant on commitment, interest and passion (p.17).

Early adopters of blended learning argued that there are many possibilities offered by the technologies for Australian educators in higher education (Garrison, Anderson, & Archer, 1999). There are several reasons behind the drive to incorporate ICT into the educational process. First, pressure to utilise ICT at a university level comes from changes in the student demography. According to Concannon, Flynn and Campbell (Concannon, Flynn, & Campbell, 2005) the surge in "full time part time students is a phenomenon of recent years, where school leavers take part-time jobs whilst attending university" (p.502). For students who work full time, the flexible design accommodates their busy schedules. Without this flexibility, the students may not be able to pursue their degrees. Blended learning environments suit students who prefer face-to-face interaction in addition to students who prefer online learning.

Second, blended learning has the potential to promote lifelong learning in higher education (Dzakiria, Wahab, & Rahman, 2012). In their qualitative study, Dzakiria, Wahab and Rahman investigated the learning experiences of a students undertaking studies at University Utara Malaysia. They found that blended learning's "flexibility nature can promote lifelong learning anywhere, and anytime" (p. 299). This is supported by research carried out by Masalela (Masalela, 2009) whose qualitative study examined factors that influenced fifteen faculty members' decision to use blended learning and found that learners become self-directed, develop critical thinking skills and become independent thinkers through blended courses. In addition, develop lifelong skills to use when they leave the university.

Third, changes in the market for delivery of education comes from innovation in new technologies. In the case of University of Central Florida (Dziuban & Moskal, 2001), a three hour classroom instruction was replaced with a two hour online instruction session. The university was able to operate multiple classes in one classroom using the technological infrastructure of the university. In addition, blended learning enables multi-university offerings (Jefferies, Grodzinsky, & Griffin, 2003) and facilitates elective courses (Verkroost, Meijerink, Lintsen, & Veen, 2008). Lastly, there is pressure from government for universities to increase participation and widen access to higher education (N. Jones & Lau, 2010).

In sum, the current environment of higher education requires a careful consideration of the role of blended learning in addressing a number issues related to teaching and learning such as generational differences, personality types and learning styles. The goal of this review is to present an investigation of the research currently available on teachers' conceptions of blended learning and their approaches to both design and teaching in higher education using Picciano's Blending with Purpose Multimodal framework. This proposes that teachers consider their objectives and understand how to apply the technologies and approaches that will work best for their students. This paper contributes to the field of blended learning by exploring how objectives from Picciano's framework affect teachers' approach to both design and teaching in face-to-face and online settings such as content, social/emotional contexts, dialectic/questioning activities, synthesis/evaluation tools, collabora-tion/student-generated content, and reflection opportunities.

Structurally, this paper consists of five thematic sections with relevant sub-sections. First, the author defines blended learning. Secondly, the advantages and disadvantages of blended learning approach will be discussed. The third section of this paper explores the literature available on teachers' conceptions on blended learning and their approaches to both design and teaching in higher education using Picciano's Blend with Purpose Multimodal framework. In the fourth section the author describes the method for choosing the studies in this literature review. The fifth section presents findings and provides suggestions for how this literature review could help researchers approach and study teachers' conceptions on blended learning environments in the future.

2. LITERATURE REVIEW

There are a few literature reviews on blended learning (Bliuc, Goodyear, & Ellis, 2007; Charles R Graham, Allen, & Ure, 2003; Shivetts, 2011; Vignare, 2007). Apart from published texts (Bonk & Graham, 2006; Littlejohn & Pegler, 2007; A. G. Picciano, Dziuban, & Graham, 2013; E. Stacey & Gerbic, 2009) there are a small number of publications focusing on teachers' conceptions using blended learning environments (Gerbic, 2011).

This section presents a critical review and synthesis of the research literature in the field being investigated by this paper: how teachers experience and perceive the blended learning approach in higher education. The literature review commences by defining blended learning. The advantages and disadvantages of the blended learning approach are then discussed. This is followed by a review of the research literature on teachers' conceptions of blended learning and their approaches to both design and teaching in higher education using Picciano's Blending with Purpose Multimodal framework.

There are many definitions for blended learning.

2.1. Defining Blended Learning

Blended learning has been defined in a number of ways and a generally accepted definition does not exist. It is used interchangeably with distance learning, online learning, eLearning, blended teaching, e-teaching, blended e-learning, hybrid learning and flexible learning. The literature defines blended learning in many different ways according to instructional methods. The three most common definitions documented by Graham, Allen and Ure (C. R. Graham, Allen, & Ure, 2005), are:

1. Combining instructional modalities (or delivery media). From a training perspective, Skill and Young (2002) view blended learning as "a combination of in-class teaching and learning modalities with robust electronically mediated experiences" (p.25). Singh (2003) sees blended learning as a combination of multiple delivery media designed to complement each other and promote meaningful learning;
2. Combining instructional methods. According to Welker and Berardino (2006) blended learning is "the use of electronic learning tools that supplement but do not replace face-to-face learning" (p.33). Blended learning is an infusion of web-based technologies into face-to-face learning to create blended learning. Alternatively the combination of instructional methods is known as hybrid learning (De Witt & Kerres, 2003; Hermann, Popyack, Char, & Zoski, 2004; Kaleta, Skibba, & Joosten, 2007);
3. Combining online learning and face-to-face instruction (Garrison & Kanuka, 2004; Ginns & Ellis, 2007; Ginns, Prosser, & Barrie, 2007; Mortera-Gutierrez, 2006; Tang & Byrne, 2007).

Wu, Tenniyson and Hsia (Wu, Tennyson, & Hsia, 2010) state that blended learning is also noted as "blended e-learning system" that "refers to an instructional system that combines multiple delivery methods, including most often face-to-face classroom with asynchronous and/or synchronous online learning. It is characterised as maximising the best advantages of face-to-face and online education" (p. 155). This view is supported by Littlejohn and Pegler (2007).

A significant amount of blended learning research has already been done from the learning context of face-to-face activities and to which an online or web-based activity had been added. Skill and Young (2002) stated that "blended learning moves well beyond the concept of bolting a Website onto a traditional classroom-based course" (p.25). Furthermore, Graham (2006) defined blended learning as "the combination of the instruction from two historically separate models of teaching and learning: traditional face-to-face learning systems and distributed learning systems" (p.5) with an emphasis on the role of computer-based technologies. However, in a criticism of blended learning, Oliver and Trigwell (2005) argued that blended learning is really concerned with the process of blending media, teaching processes and presentation, rather than student's learning. They suggested that blended learning could be redeemed "by a closer analysis of the critical aspects of the subject matter that are in variation in the act of using blended learning" (p.24). Furthermore, Garrison and Kanuka (Garrison & Kanuka, 2004) state that blended learning should not be "just adding on to the existing dominant approach or method" (p.97) but should be transformative in higher education and increase the opportunities for critical and reflective thinking.

In a major review of blended e-learning in the UK, Sharpe (2006) concluded that while the term "blended learning" was unclear, it remained a practical term, because it could mean different things to different people. The term 'blended learning' is used in this paper to describe learning activities that involve a combination of face-to-face interactions and technologically mediated interactions between students, teachers and learning resources (Bliuc et al., 2007).

As described above, there are many variations in defining blended learning and different institutions implement blended learning approaches in different way (Delialioglu & Yildirim, 2008).

2.2. Advantages of the Blended Learning Approach

It has been widely argued in the literature that there are four main advantages for teachers to incorporate the blended learning approach into teaching practice:

1. Greater flexibility of time. Freedom for students to decide when each online lesson will be learned (Bouhnik & Marcus, 2006; Demetriadis & Pombortsis, 2007);
2. Lack of dependence on the time constraints of the teacher (Edginton & Holbrook, 2010; Lock, 2006);
3. Time for reflection. Freedom for students to express thoughts, and ask questions, without limitations (Chamberlin & Moon, 2005; Liaw, Huang, & Chen, 2007);
4. Meeting different needs and learning styles (Ho, Lu, & Thurmaier, 2006).

These advantages can support students to develop more responsibility for their learning (Rodriguez & Anicete, 2010) and improve critical thinking (Saundercook & Cooper, 2003). These perceptions are consistent with the literature that suggests that the blended learning approach can transform learning experiences (Garrison & Anderson, 2003; Knight, 2009). In particular, it has been argued that the blended learning approach can improve students' written communication skills, problem solving skills, and increase the opportunities for critical and reflective thinking (Garrison et al., 1999). Lapadat (Lapadat, 2002) found that with asynchronous text-based communication students have the time to carefully compose their thoughts and ideas into a written-form communication. This attention to writing, in combination with asynchronous communication, provides students with opportunities for critical reflection which is necessary for higher-order thinking (Garrison & Anderson, 2003).

The blended learning approach can provide students access to online learning materials and engage learners interactively (Concannon et al., 2005; Sharpe, 2006). Motteram (2006) found that the blended learning approach enhanced the learning experience as the course structure enabled them to deal with topics in their own time and to organise themselves better around the tasks in their own time. In two studies, one in the UK and one in Australia, the use of blended learning environments together with access to online learning materials were found to be determining factors behind increased student engagement and motivation (Concannon et al., 2005; De Lange, Suwardy, & Mavondo, 2003). In keeping with Motteram observations, (2006) Rodriguez and Anicete (2010) found that the blended learning approach enhanced the learning experience as the course structure enabled students to deal with topics in their own time and to organise themselves better around the tasks in their own time. Rodriguez and Anicete (2010) also argue that learning management systems, such as Modular Object Oriented Dynamic Learning Environment (MOODLE), can support students to develop more responsibility for their learning. This view is supported by Masalela (Masalela, 2009). Furthermore, Garrison and Anderson (2003) argue that access to information is an important part of learning however student's learning is largely achieved through engagement and interaction with other students. This view is supported by Chen and Looi (Chen & Looi, 2007) who indicated that online discussion contains more opportunities for the practice of in depth clarification and inference skills.

The younger generations according to Prensky's (2010) "digital natives" use online technologies for their social and informational activities whilst older generations use these technologies less so. Furthermore, students engage in ways they prefer according to their preferences, interests or abilities.

The blended learning approach can meet the different needs and learning styles of students. Kupetz and Ziegenmeyer (Kupetz & Ziegenmeyer, 2005) discussed and evaluated a model of blended learning for teaching English and focussed on how different types of learners can be supported and their research covers a wide range of activities: classroom recordings, multimedia-based case stories, electronic interviews and mini-practices. Each of these activities was designed to support different aspects of student learning and to be flexible enough to respond to the needs of different types of learners. Similarly, Julian and Boone (2001) found that "the importance of a blended learning approach to learning is that it ensures the widest possible impact of a learning experience" (p. 58) and proves to be very useful in improving teachers' abilities to respond a wide range of students' needs. In addition, Ho (2006) found that blended learning courses result in lower dropout rates compared to fully online courses. This view is supported by Dzuiban and Moskal (Dziuban & Moskal, 2001) who reported that students' withdrawal rates were reduced in blended learning courses.

Research literature elsewhere indicates that the blended learning approach can bring teachers and students closer together (Aspden & Helm, 2004; Graetz & Goliber, 2002). Aspden and Helm (2004) explored student engagement and interaction with students in the context of a blended learning situation and argue that the blended learning approach can help bring teachers and students together by making appropriate use of a mix of technologies students can feel increased connectivity with both their fellow students and university staff.

To increase the likelihood of positive student learning outcomes using the blended learning approach teachers must adopt new technologies (Piccoli, Ahmad, & Ives, 2001). Teachers publish their learning resources in learning management systems and students participate through computer networks. Teachers who use a learning management system can share course materials, syllabus, opinions and online assessments as well as use e-mail, discussion boards, calendars, blogs, journals, along with traditional face-to-face activities such as lectures and tutorials. Simply placing existing material online does not serve the students. Gerbic (2011) refers to this as "juxtaposition of two pedagogical settings" (p.222). Instead, the focus should be on recognising the potential of the blended learning approach to enhance student's learning outcomes. Garrison and Vaughan (2008) state that blended courses require these elements:

1. In-class activities that link the online assignments so as to reinforce the intent of activities outside the classroom;
2. Shift from teacher-centred to learner-centred activities in class as well as online;
3. Focus on student responsibility for navigating online resources and conducting online research; and
4. Evaluation instruments that provide frequent feedback.

A positive attitude towards computers and the Internet, for example, where teaching staff are not afraid of the complexity of using computers, will result in effective learners in a blended learning environment (Piccoli et al., 2001). Research results suggested that applying online technology in the classroom enhances students' achievement (Masalela, 2009). Evaluation instruments can provide frequent feedback such as an electronic grade book that captures students' accomplishments, reviewing course materials and communicating with teachers can be carried out more efficiently. In their quantitative study Amrein-Beardsley, Foulger and Toth (2007) investigated nine instructors perceptions of their students' and their own experiences with hybrid courses. From the questionnaires they concluded that students found the online grade book and announcements most useful. Students appreciated instructors who graded assignments and posted them in the grade book in a timely and efficient manner. Students found the course document downloads, Internet sites and links sent to them from the instructors equally useful in terms of technology tools that enhanced their learning.

Despite these advantages for teachers to incorporate the blended learning approach into teaching practice, thorough reviews of the literature have yet to show a reliable body of knowledge indicating that these benefits are an outcome for all students. Much of the research on blended learning reveals that deep learning is not easily achieved using the blended learning approach

(Garrison & Vaughan, 2008; Kanuka, 2008). These findings are consistent with prior research that has shown that these benefits are not easily achieved in face-to-face teaching (Biggs, 1999; P. Ramsden, 1991).

Other authors found that blended learning courses had negative outcomes.

2.3. Disadvantages of the Blended Learning Approach

A review of the literature suggests that there are five disadvantages for teachers to incorporate the blended learning approach into teaching practice:

1. Possibility of negative effects such as innovation fatigue amongst staff and students (Oliver & Trigwell, 2005);
2. Not enough guidance for students;
3. LMS technical issues;
4. Lack of interaction on the LMS; and
5. Unsatisfactory use of the face-to-face teaching time (Heinze & Procter, 2004).

Research indicates students' attitudes towards computers and the Internet is an important factor in the effectiveness of the blended learning approach (J. Arbaugh et al., 2009) (J. B. Arbaugh, 2002; Garrison & Vaughan, 2008; Piccoli et al., 2001; Sharpe & Benfield, 2005). Furthermore, several researchers indicate that technology quality affects student satisfaction with blended learning environments (Piccoli et al., 2001; Webster & Hackley, 1997). Research has shown that the learning environment is an alterable educational variable that can directly influence student outcomes (Waxman, Huang, & Wang, 1997).

Furthermore, studies have suggested that, in addition to adjusting to the technology delivered instruction, students must also adapt to the "learning approach" adopted by the tertiary institution. According to Garrison and Vaughan (2008, p. ix) "those who have grown up with interactive technology are not always comfortable with the information transmission approach of large lectures. Students expect a relevant and engaging learning approach" (p.ix). The idea of the "digital native" (Prensky, 2001) suggests that students will be able to use online methods of engagement, such as blogs, social media, wikis and mobile devices effectively and efficiently having grown up with the technologies. Prensky (2006) argues "today's students are no longer the people our educational system was designed to teach" (p. 2). This suggests that students who have grown up with technology may be better suited to the blended learning approach (Laurillard, 2002; Palloff & Pratt, 1999).

Elsewhere in the literature, Chen and Looi (Chen & Looi, 2007) found that in-class online discussion lacked interaction, because most of the online postings were task oriented, independent postings without replies and comments on postings by others. Secondly, too much online discussion in-class may slow the progress of the class. Thirdly, in-class online discussion does not assure that every learner will read the online postings, because reading online discussion was not a compulsory practice. Chen and Looi (Chen & Looi, 2007) research examined how to incorporate online discussion in a face-to-face classroom learning study comprising of sixteen Heads of Departments of Information Technology from Singapore schools who attended a professional development course. These findings are consistent with Collis et al's (Collis, Bruijstens, & van Veen, 2003) statement that online learning often requires a large amount of self discipline on the part of the learners and Salmon (Gilly Salmon, 2002) who states that one of the main disadvantages of blended learning is the lack of interaction between students. In addition, Ellis and Calco (R. Ellis & Calvo, 2004) found that undergraduate students could not connect the discussions in face-to-face teaching time and online to the goals of the course. These finding are consistent with Molesworth (Molesworth*, 2004) who found a lack of participation in computer-mediated classes with students wanting more integration into the overall course.

It has been suggested in the literature that teachers require better skills to incorporate the blended learning approach in their teaching (Coates et al., 2005). Salmon (2005) states that uploading PowerPoint slides into the learning management system is not enough to create good quality online learning materials. This view is supported by Heinze and Proctor's action research study that examined staff opinions regarding the delivery of a program at the University of Salford using blended learning. Heinze and Proctor (2004) found that simply using a learning management system instead of web pages to deliver handouts and presentations and combining it with discussion boards resulted in staff stating that they were not really doing any e-learning on the course.

Picciano's Blending with Purpose Multimodal model was derived from discussions above on blending learning environments, generations, personality types and learning styles.

2.4. Blending with Purpose: The Multimodal Model

The structure of this paper is based on Picciano's Blending with Purpose Multimodal framework (see Figure 1). Picciano (2009) Blending with Purpose Multimodal framework recognises that because students represent different generations, different personality types, and different learning styles, teachers should seek use multiple approaches including face-to-face methods and online technologies to meet the needs of a wide scope of students.

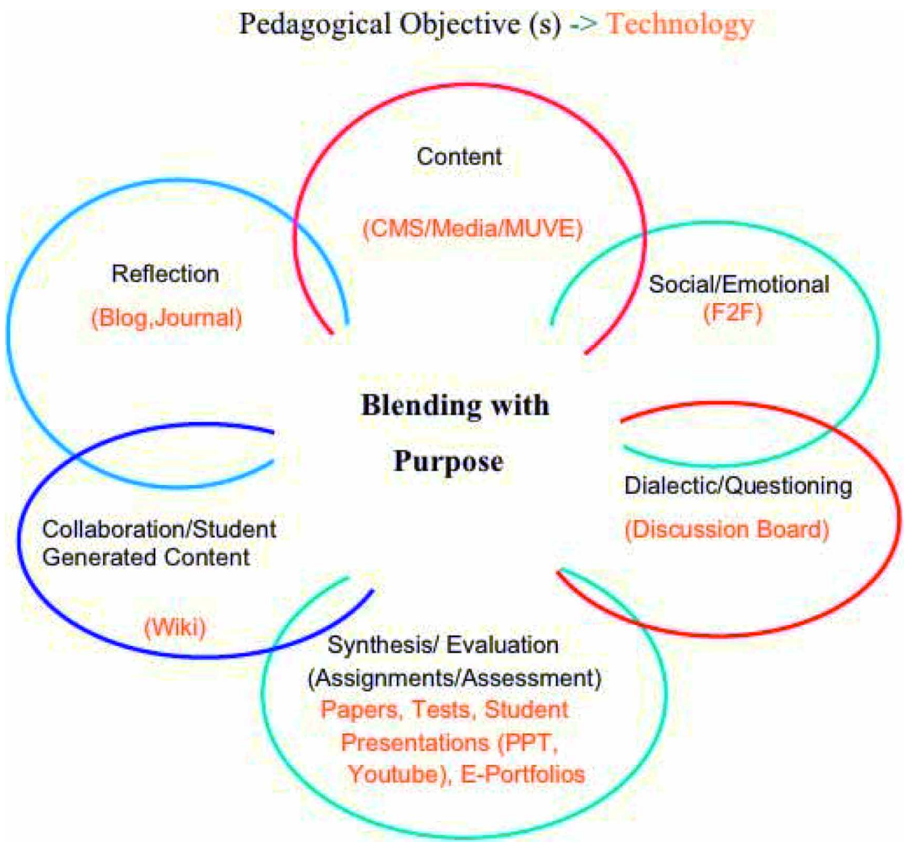
A significant component of this model is that teachers need to carefully consider their objectives and understand how to apply the technologies and approaches that will work best for their students. There are six pedagogical objectives used in the model shown in Figure 1: content, social/emotional contexts, dialectic/questioning activities, synthesis/evaluation tools, collaboration/student-generated content, and reflection opportunities. Learning management systems and other online tools provide a number of mechanisms for assisting teachers meet these objectives.

2.5. Teachers' Conceptions of Blended Learning

Considerable research has been carried out into teachers' conceptions of face-to-face teaching (Paul Ramsden, 2003; Saljo, 1979; Trigwell, Prosser, & Taylor, 1994) and what impact this may have on the way university teachers carry out their teaching. Entwistle (2005) suggests that there are relationships between teachers' conceptions of teaching (including their beliefs about teaching) and their approaches to teaching. An understanding of teachers' conceptions is therefore likely to help in the process of understanding and improving teaching (Prosser, Trigwell, & Taylor, 1994). Kember and Kwan (2000) identified two main approaches to teaching: 'content centred', in which teachers focus on the content to be taught; and 'learner centred' where teachers focus on the learning process.

As this literature review shows, there are thirteen studies focussed on teachers' conceptions, beliefs and experiences of blended learning and their approaches to both design and teaching in face-to-face and online settings. Teachers' conceptions of blended learning have been investigated with five studies reported research into teaching with e-learning (R. A. Ellis, Steed, et al., 2006; Gonzalez, 2009; Lameras, Paraskakis, & Levy, 2008; McConnell & Zhao, 2006; Roberts, 2003). From these five studies, one had been conducted in a 'distance education' setting (Gonzalez, 2009) and one reported conceptions of blended teaching (R. A. Ellis, Steed, et al., 2006). A couple of studies have investigated teachers' "beliefs", which are considered different from "conceptions" according to the literature (Elizabeth Stacey & Wiesenberg, 2007; Steel, 2009). The six remaining studies focussed on teachers' conceptions and experiences of working with learning management systems (Gedik, Kiraz, & Ozden, 2013; Jokinen & Mikkonen, 2013; King & Arnold, 2012; McShane, 2004; Napier, Dekhane, & Smith, 2011; Ocak, 2011).

Figure 1. Blending with purpose: The multimodal model (Source: A. Picciano, 2009, p.11)



Picciano's (2009) Blended with Purpose Multimodal framework comprises of six objectives: content; socially and emotionally; dialectic/questioning; collaboration; synthesis/evaluation and reflection. These six objectives affect teachers' approaches to both design and teaching in face-to-face and online settings. Much of the research in one objective impacts the other objectives.

First, the Blending with Purpose Multimodal framework suggests that delivering content is one of the main objectives of teaching and there are many ways in which content can be delivered and presented to students. Blended learning allows teachers an ongoing opportunity to experiment with new approaches to learning and introduce new types of educational technology into their teaching such as the Web and learning management systems. Learning management systems enable the delivery of a variety of media including text, video and audio. In providing and presenting content, the Blending with Purpose Multimodal framework suggests that multiple technologies and media be utilised. Research results suggest the teachers' conceptions of blended learning as a way to provide information to students by way of lecture notes, online learning resources and links to external websites (McConnell & Zhao, 2006; Oh & Park, 2009; Roberts, 2003).

McConnell and Zhao (2006) research examined the ways in which Chinese higher education teachers think about e-learning and e-teaching, and the ways in which they implement e-learning in a qualitative study. From twenty-four interviews they found a set of categories of conceptions:

1. The centrality of the learner (p.516);
2. Online co-operative learning (p.517);
3. Network learning (p.518);
4. Student learning (p.518);
5. Infrastructure and access (p.519).

Their research findings suggest that face-to-face instruction using lectures were the preferred method of teaching with each teacher acknowledging the "sheer power of the lecture in the Chinese higher education system" (p.519). These results are supported by another study that examined faculty involvement in blended instruction and their attitudes towards the instructional method. Oh's (2009) quantitative study involved one hundred and fifty-one universities classified by the Carnegie Foundation. One hundred and thirty-three faculty members completed a survey and reported that the most commonly selected instructional delivery format used by faculty was "face-to-face instruction with supplementary online instructional components" (p.333). These results suggest that e-learning is conceived by teachers as not a good way to deliver course content to students with teachers preferring face-to-face methods.

In addition, Robert's (2003) phenomenographic study investigated the use of e-learning for teaching and the extent and nature of Web use for teaching and learning in a Scottish university. From a Web-based survey and interviews with seventeen teachers three conceptions of teaching using the Web were discovered, as well as a set of strategies to describe the approaches taken by lecturers. Conceptions of teaching using the web that were discovered are:

1. The web as a source of subject information (p.145): in this conception the Web is used the medium used to distribute information to students. Teachers upload learning materials such as lecture notes and direct students to websites to retrieve information;
2. The web is used for individual and independent self-paced learning (p.146): students use the Web to complete subject activities;
3. The web is used for group analysis, decision making and dialogue (p.147): the Web is used for students to interact with one another and create communities of inquiry (Garrison & Arbaugh, 2007).

These conceptions are consistent with McConnell and Zhao (McConnell & Zhao, 2006) definition of networked learning and Picciano's definition of content (A. Picciano, 2009) where teachers place material online and students are expected to learn at their own pace. At the University of Central Florida, learning to use technology to modify their teaching methods was cited as one of the outcomes that faculty liked most about teaching on the Web (Dziuban & Moskal, 2001). The fundamental principles underlying networked learning are learner-centred where the learning is outcome-focused and requires engagement, group collaboration and the creation of communities of inquiry (Garrison & Arbaugh, 2007).

Research results from this study are consistent with previous research outcomes from Kember and Khan (2000) who suggested that teachers rely on 'content-centred' approaches to transmit information to students. Like Roberts and McConnell and Zhao, Gonzalez also found teachers' conceptions focused on access to learning materials and information transfer. Gonzalez's (2009) phenomenographic study investigated what university teachers think eLearning is good for in their teaching. From interviews with seven teachers from the Faculty of Health Sciences three conceptions using eLearning were identified:

1. For individual access to learning materials and information, and for individual assessment (p.312);
2. For learning-related communication (p.312);

3. For networked learning (p.312).

Gonzalez (2009) found that university teachers "having a 'content-centred' approach to teaching can be defined as 'informative-individual learning focused'; while those university teachers having a 'transitional or learner-centred' approach can be defined as 'communicative-networked learning focused'" (2009, p. 311).

Similar to the 'content-centred' conceptions found in the above studies, outcomes from Lameras, Paraskakis and Levy (2012) showed that teachers conceived eLearning as a way to transfer information to students where learning resources were uploaded for students to use on their own. This enables students to learn at their own pace. Lameras, Paraskasis and Levy (2012) qualitative study investigated Greek university teachers' conceptions of and approaches to teaching using digital technology in blended settings. Their interviews with twenty-five Computer Science teachers identified four categories that describe the use of virtual learning environments as a means of supporting:

1. Information transfer (p.145);
2. Application and clarification of concepts (p.145);
3. Exchange and development of ideas, and resource exploration and sharing (p.145);
4. Collaborative knowledge-creation, and development of process awareness and skills (p.145).

The first and second category of conceptions support the content-centred approaches of the virtual management system and are supported by research carried out by McConnell and Zhao as well as Roberts (McConnell & Zhao, 2006; Roberts, 2003).The third and fourth category of conceptions support the learner-centred of the virtual management system and are supported by research carried out by Ellis, Steed and Applebee as well as McConnell and Zhao (R. A. Ellis, Steed, et al., 2006; McConnell & Zhao, 2006).

Second, the Blended with Purpose Multimodal framework suggests that email and electronic communications enable collaboration between students. Research results indicate teachers' conceptions of 'eLearning as a way to engage in communication-collaboration-knowledge building' (Gonzalez, 2010) and seen to engage students in discussion, developing understanding and building knowledge (R. A. Ellis, Steed, et al., 2006). In addition, blended learning is conceived as a way of engaging students in learning activities that may lead to higher-level learning experiences (Garrison & Kanuka, 2004).

In their qualitative study, Ellis, Steed and Applebee (2006) investigated the conceptions of blended learning and teaching by teachers in two campus-based Australian universities, and the relationships between these conceptions to their approaches to integrating online and face-to-face environments. From their interviews with twenty-two teachers they identified four conceptions of blended teaching:

1. Blended teaching as helping students develop and apply new concepts (p.324);
2. Blended teaching as developing student understanding through aligning media to intended learning outcomes (p.324);
3. Blended teaching as providing students with information (p.325);
4. Blended teaching as replacing part of the responsibility of being a teacher (p.326).

The researchers found that teachers recognised a connection between students achieving their learning outcomes and the role of technology in blended settings helping students develop higher order thinking. Garrison and Kanuka (2004) argued that blended environments can support and transform universities by building a Community of Inquiry (Garrison & Arbaugh, 2007) and develop higher order thinking.

Third, the Blending with Purpose Multimodal framework suggests that the social and emotional needs of students should be considered by teachers when designing blended learning courses (McShane, 2004; Elizabeth Stacey & Wiesenberg, 2007). Stacey and Weisenberg (2007) study investigated teachers' beliefs about teaching face-to-face and online in two case studies of ten Australian and twelve Canadian university teachers. From an online open-ended questionnaire about teaching philosophies and approaches together with the Teaching Perspective Inventory which measures teachers beliefs. They found that twenty-two teachers regarded themselves as more teacher-centred in face-to-face settings and more learner-centred in online settings. The Australian teachers had a preference for teaching face-to-face because they believed that it enabled them to build better relationships with their students. In contrast, the Canadian teachers had a stronger preference for teaching online because they believed the mode could support multiple perspectives.

These conceptions are supported by research carried out by McShane's (2004) case study that investigated the personal experiences of five Australian lecturers who teach using an online learning management system (Web CT or Top Class) to organise the online components of their subjects. Five themes emerged across the individual case studies:

1. Enhanced relationships with students (p.8);
2. Planning and teaching becomes very conscious tasks (p.9);
3. Expansion, extension, augmentation (time and space) (p.10);
4. Scrutiny and reflexivity (p.11);
5. The centrality of learning (p.12).

McShane (2004) found that university teachers perceived their teaching approaches where no different when they were teaching face-to-face to when they were teaching online. These findings were inconsistent with studies identified in this literature that show that teachers' approaches can differ considerably when changing modes of teaching.

The fourth objective from the Blending with Purpose Multimodal framework suggests that dialectic/questioning is an important activity that allows faculty to explore what students know and to refine their knowledge. For dialectic and questioning activities, a well- organised discussion board activity generally seeks to present a topic or issue and have students respond to questions, provide their own perspectives while also evaluating and responding to the opinions of others (Steel, 2009). Research results indicate that teachers are advised to take deliberate action once courses begin towards creating a community of inquiry (Garrison & Arbaugh, 2007) such as monitoring and responding to online discussion board postings (Conrad, 2005).

Steel (2009) investigated the relationship between teacher beliefs and their learning designs for learning management systems in large undergraduate classes in her qualitative study. Three award winning university teachers from an Australian university were interviewed. The research identified "strong affective components" (p.414) of the teachers' belief systems that demonstrate a commitment to engage with their students, build learning communities and use technologies to support social justice and equity. Faculty who have taught blended learning courses have observed that students do a better job of writing, learning course material, mastering concepts, and applying what they have learned compared to traditional face-to-face courses (Aycock, Garnham, & Kaleta, 2002). This viewpoint is captured in a comment from a faculty member at the University of Wisconsin who teaches blended courses, "My students have done better that I have ever seen; they are motivated, enthused and doing their best work" (p.3).

The fifth objective from the Blending with Purpose Multimodal framework suggests that students receive feedback from teachers regarding their academic progress. Learning management systems provide a number of mechanisms for assisting teachers to assess their student's learning and provide feedback. Major methods include electronic tests, assignments and portfolios (Gedik et al., 2013; Jokinen & Mikkonen, 2013; King & Arnold, 2012). In sum, learning management systems provides an on-going record that can be referred to over and over again by both students and teachers. Gedik, Kiraz and Ozden (2013) qualitative study investigated instructor experiences relating to the design, development and implementation processes of a blended course. They found several themes emerged: arousal of student's interest and participation, flexibility, time conservation, improvement of interaction, collaboration and communication opportunities and the ability to track student's progress.

In another qualitative study, King and Arnold (2012) explored five professors who teach in blended learning environments and examined whether course preparation and design, communication and motivation are taken into consideration when designing their courses. All the professors used a learning management system for the online component. From a survey and interviews with five professors from the college of education at a Mid-western research university, four factors were found to contribute to the success of blended learning courses:

1. **Course Preparation (p.51):** The professors prepared their blended courses in various ways and used technology, such as Skype, wikis and blogs in addition to the learning management system;
2. **Course Design (p.52):** The professors used the content feature of the learning management system to post course documents and assignments which support the content-centred approach of teaching (Kember & Kwan, 2000);
3. **Communication (p.53):** The importance of communicating with students in a timely manner is consistent with research findings in blended learning Ho, Lu and Thurmaier (Ho et al., 2006). The professors used the discussion board in various ways. One professor required the students to complete weekly journals that were viewed by student and professor only enabling a confidential dialogue and the student's time to reflect on what they had learnt;
4. **Motivation (p.53):** These results are supported by research carried out by Aycock, Garnham and Kaleta (Aycock et al., 2002).

According to King and Arnold (King & Arnold, 2012) "preparing for a blended learning course requires more discipline and preparation time than a traditional face-to-face course" (p.51). The literature records challenges to the use of blended learning environments in other studies. The commonly found issues were increased time commitment and workload (Edginton & Holbrook, 2010; Gedik et al., 2013; King & Arnold, 2012; Napier et al., 2011). The increased time commitment involved in designing a blended course is regarded as the number one challenge by faculty (Dziuban & Moskal, 2001). This view is echoed in Napier (2011) research (discussed below) where several success factors for teaching and designing blended learning courses were identified:

1. Play to your strengths;
2. Utilize technology;
3. Build a classroom without walls;
4. Provide tutoring and on-line support;
5. Creatively manage out-of-class time.

Napier (2011) examined the perceptions of instructors teaching blended learning courses at a small public liberal arts college and found that instructors invest more time becoming familiar with available technology, creating in-class activities and reflecting on course structure. These results are also supported by research carried out by Edginton and Holbrook (2010) who found that teachers teaching blended learning courses can expect to invest more time becoming familiar with available technology and creating in-class activities. These research results contradict Garrison and Vaughan's (2008) argument. They argued that, blended learning environments can ease the workload. Similarly, all faculty members involved in a blended learning program at the University of Wisconsin, Milwaukee stated that they will continue to teach blended learning courses as they believe that their time was wisely invested in improving the learning environment for both students and faculty members (Aycock et al., 2002).

Jokinen and Mikkonen (2013) qualitative study described teachers' experiences of planning and implementing teaching and learning in a blended learning based nursing programme. Nine themes emerged from the data including: collaborative planning; integration; student group; face-to-face teaching; online learning; learning activities; teaching and learning methods; learning in and about work; and confirming competences (2013, p. 526).

These researchers found that teachers experienced the blended learning approach positively despite challenges from the viewpoint of planning and design. According to the study careful planning is required by teachers to ensure the combination of face-to-face learning and learning in practice with technology-mediated learning activities. These findings are supported by previous studies of Salmon (2005) as well as Heinze and Proctor (2004). Moreover, while planning for blended learning, teachers should include a variety of learning activities to meet the needs of different learners (A. Picciano, 2009).

Lastly, the Blending with Purpose Multimodal framework suggests that the ability to share one's reflection with others can be most beneficial however this objective is the least researched objective. Pedagogical activities that require students to reflect on what they are learning and to share their reflection with their teachers and fellow students are viewed very positively. Blogs and blogging, whether as group activities or for individual journaling activities, are appropriate tools for students reflecting on what is being learned. Ocak (2011) qualitative study examined problems and challenges faculty members encountered in blended learning environments and found class discussions that take place on discussion boards or blogs and provide teachers with an electronic record that can be reviewed over and over again to examine how students have participated and progressed over time.

These predominantly qualitatively studies draw attention to the importance of teachers' conceptions and beliefs of teaching in face-to-face and online settings.

3. METHOD

A comprehensive literature review was conducted to locate papers on teachers' perceptions on blended learning using search engines and educational databases such as Academic Search Elite, ProQuest, ERIC (Education Resources Information Centre), and Google Scholar. The keywords used were blended learning, blended learning environments, blended teaching, online teaching, eLearning, teacher perceptions, teachers conceptions (as well as combinations of these). Literature related to teachers working across face-to-face and online environments were included in this review.

Selecting only those papers, which specifically focussed on blended learning in higher education, and reported the results of empirical research, further refined this search. Conference papers and dissertations were not included. References from the articles included in the review were examined in order to identify other relevant studies. Following this literature search a database including approximately ninety-seven titles was created using EndNote.

There are four published texts (Bonk & Graham, 2006; Littlejohn & Pegler, 2007; A. G. Picciano et al., 2013; E. Stacey & Gerbic, 2009); there were few publications, which directly discussed teacher's perspectives on blended teaching.

4. DISCUSSION

Blended learning research on teachers' conceptions, beliefs and experiences of teaching in face-to-face and online settings reflects all six objectives of the Blending with Purpose Multimodal framework but student-generated content and reflection were not used to their fullest capacity. Teachers focused mainly on content, social/emotional aspects of blended learning courses for their students, and synthesis/evaluation tools. The studies in this literature review contained faculty-driven rather than student-generated content, as was suggested by Picciano (2009) as part of the design of the multimodal model. This literature review shows the importance of teachers' conceptions, beliefs and experiences and their approaches to both designing and teaching in face-to-face and online settings including learning management systems. In addition, relationships between conceptions and approaches found in previous research have been confirmed. Research results indicate that teachers use multiple approaches including face-to-face methods and online technologies that address the learning needs of a variety of students from different generations, personality types and learning styles.

Even though these studies have been conducted in different settings and by different researchers, many similarities in research results can be seen. Research results indicate that teachers merge several objectives of the Blending with Purpose Multimodal framework together to create learning experiences. Teachers utilise multiple approaches and technologies as a way to transfer information to students. Learning resources are uploaded for students to use on their own and teachers provide information to students in the form of lecture notes, online resources and websites. This enables students to learn at their own pace. Teachers can engage in communications and learning activities with students including email, blogs and discussion boards. Electronic communications enable collaboration between students. Teachers develop pedagogical activities that require students to reflect on what they are learning and to share their reflection with their teachers and fellow students are viewed very positively. Teachers use discussion to present a topic or issue and have students respond to questions, provide their own perspectives while also evaluating and responding to the opinions of others.

The research in blended learning so far has focused more on what teachers need to know in order to integrate technology into their teaching (Mishra & Koehler, 2006) rather than on personal support tools to enable students to use blended learning environments effectively and to learn efficiently. Most studies have been conducted as case studies. Yin (2009) argued that “a case study investigates a contemporary phenomenon within its real-life context” (p.13). Even though the case study has this advantage, this research area needs other research methods. The Blending with Purpose Multimodal framework used in this paper can be used as a conceptual framework to examine the effectiveness of blended learning courses. The Blending with Purpose Multimodal framework shows what objectives teachers should consider when designing blended learning courses.

As this literature review shows, teachers' conceptions and approaches to both design and teaching using blended learning environments is still a developing issue. More research is also needed to gain a more comprehensive understanding of teachers' perceptions and problems that these teachers face when integrating pedagogy and content knowledge into blended learning environments, the strategies they employ to address these problems, and how they use the blended learning tools (e.g., learning management systems) to overcome these challenges. Discovering what type of pedagogical and technology changes are being made to blended learning courses, being able to identify design problems, and finding solutions to design and development issues are extremely important to blended learning. The Blending with Purpose Multimodal framework (A. Picciano, 2009) should also be compared to other frameworks to discover to what extent pedagogical frameworks are helping teachers to integrate pedagogy and content knowledge into blended learning environments.

Chapter 2
Flipping STEM Learning:
Impact on Students' Process of Learning and Faculty Instructional Activities

ABSTRACT

The call for reform in education, based on the recognition of an increased role of technology, as well as the rapid advancement of technology types and uses, requires major changes to traditional methods of teaching. The purpose of this chapter is to present the results of the use of a flipped classroom approach in a higher education STEM course. The chapter includes information on the development and structure of the flipped classroom, the role of video lectures and active learning in supporting flipped instruction, the value of prior experience as a concomitant variable, and the benefits and limitations of the approach. Examination of findings supports this new method of instruction and learning; however, some student hesitance to move beyond traditional instruction suggests a need to implement the approach as a continuum, beginning with segments, then moving to a blended technique, with final transition into a totally flipped classroom. This process supports instructor development and student buy-in while allowing for formative assessment of resources and increasing of student efficacy.

INTRODUCTION

The need for educational reform is well recognized (Tucker, 2012), and plans for change are in place all over the nation, at all levels and all sites—Pre-K-12 schools, institutions of higher education, states' department of education, and federal offices that support education (United States Department of Education, 2010). These plans for reform include not just what we teach but how we teach. The ultimate goal of this systemic change in education is twofold:

DOI: 10.4018/978-1-4666-8246-7.ch002

to improve our nation's economic growth and to cultivate the collaboration skills necessary for international problem-solving (United States Department of Education, 2010).

As we strive to reach this goal, we must also deal with the changing context. Because of rapid gains in both the amount of information and sources for information transmittal, today's students come to learning with a very different skillset than did students who attended school just a decade ago. In addition, there is a very different recognition of what skills need to be acquired for future success in society. On a micro-level, students' future skills must include knowing how to problem-solve, how to successfully work both alone and on collaborative teams, how to think independently yet access diverse external resources, and how to adjust to an ever changing environment (Keengwe, Onchwari, & Onchwari, 2009; Salomon, 2002). On a macro-level, all students must be able to support and add to a highly knowledgeable workforce, heavily based in Science, Technology, Engineering, and Math (STEM).

The call for change in education, based on the recognition of this increase in the role of technology and the rapid advancement of technology types and uses, requires major modifications to traditional methods of teaching and the expected outcomes. Students must not only learn, but also learn how to learn. Increased engagement of students is paramount; in helping students learn how to learn, students must actively construct, and want to construct a flexible knowledge base. Research tells us that increased engagement can be promoted through instructional strategies using visual stimulation, experiential/authentic learning, technology integration, and community-based learning (Brown, Hansen-Brown, & Conte, 2011; Newman, Clure, Deyoe, & Connor, 2013; Newman & Gullie, 2009). Adaptations of these techniques as well as new instructional strategies, particularly in STEM classrooms, are needed; especially strategies that cultivate a student-centered learning environment that promotes proficiency and expertise in subject matter, dissuades the passive learning of teacher-centered direct instruction, and develops the ability to continue lifelong learning of both content and application (Newman et al., 2013). The flipped classroom approach, when integrated with increased hands-on application, is one instructional method currently being explored as a means of meeting the demand for twenty-first century classrooms to provide active and engaging knowledge construction.

The purpose of this chapter is to present the results of the use of a flipped classroom approach in a higher education STEM course. The chapter includes information on the structure of the flipped classroom, the role of video lectures in supporting flipped instruction, and the benefits and limitations of the approach.

BACKGROUND

Research suggests that the growth in technology-related jobs will grow from 50 to 77% over the next decade, making it crucial for educators to prepare students for these jobs (Tucker, 2012). This need calls for an integrated approach to content and technology that will foster knowledge, application, and the ability to continue learning. Brown and colleagues (2011) note that emphasizing a productive interconnected learning environment promoting content and technology skills not only supports, but enhances students' learning, particularly when that setting involves a flexible, but personalized collaborative scenario. This type of student-centered, technology-based, active learning relies on students wanting to take control of their learning; this includes setting their own goals, monitoring their own progress, and facilitating their own and others' critical thinking and problem solving skills (Zimmerman, 1995). Many secondary schools have adopted technology as a way to support and cultivate students' interests and to help develop the skills needed for success in society. The implementation of what are now called *flipped classrooms*, piloted by Bergmann and Sams, two high school chemistry teachers in Colorado, is an innovative technique that enhances content-based learning, while offering more time for individualized practice and skills acquisition (Simba Information, 2011).

In its most progressive use, a flipped classroom relies on technology to introduce students to concepts and content outside of the formal educational setting. This digitally supported introduction, usually occurring before practice, is the new out-of-class homework. Instead of listening to a lecture in class and practicing on their own outside of class, basic transmittal of concepts and instruction take place outside the classroom and in-class instructional time is now used for active experimentation (both autonomous and collaborative) that promotes critical thinking. This in-class application provides time and opportunities for students, and instructors to interact on direct use and concept application, building on and enhancing what is learned and reinforced via outside lectures (Bull, Ferster, & Kjellstrom, 2012; Fulton, 2012; Simba Information, 2011; Strayer, 2012). Flipping the classroom, moving lectures outside and practice, experimentation, and rehearsal inside, allows instructors more time to promote and monitor student understanding through direct questioning, by facilitating collaborative activities, and providing one-on-one attention as needed (Bull et al., 2012; Carpenter & Pease, 2012; Pape, Sheehan, & Worrell, 2012; Rycik, 2012). These flipped classroom practices support the use of integrated constructivist and constructionist-based approaches to learning and practices; methods that have been shown to yield greater student inquiry and the acquisition of more practical knowledge of content, which in turn, have been shown to produce greater proficiency and expertise (Clinton & Rieber, 2010; Guthrie, 1952; Vygotsky, 1978).

Higher education, especially STEM education, is now beginning to reconsider and revise uses of already extant characteristics similar to those used in the flipped approach developed for secondary education. For instance, many post-secondary sites are already using the Internet as a means of supporting learning, thereby offering students the flexibility in scheduling and diversity in courses needed to pursue an accredited degree (Phillips et al., 2007). A variety of educational technological resources have emerged to support this effort. For example, learning management systems, such as Blackboard's™ Learning Management System, are highly utilized in higher education along with other open-source communication and information sharing methods. Additionally, educators are implementing and refining the use of an array of multimedia approaches that supplement traditional classroom-based activities such as online discussion, active links, simulations, synchronous communication, tutorials, and videoconferencing (Cook, Garside, Levinson, Dupras, & Montori, 2010; Donahue & Crosby, 2013). The acceptance of implementing these techniques within instructional practices has not been as difficult as first feared. Because these types of technology also are being implemented at K-12 levels to enhance instruction, many students come to higher education settings expecting instruction to reflect these methods. As a result, the use of already well-accepted technology resources when providing content should facilitate the transition to technology supported flipped classrooms for both students and instructors (Cheng, 2006; Swan, 2011).

Another already extant characteristic that can easily be adapted in STEM higher education is the use of problem-solving tasks. Hands-on, constructivist activities already have been found to promote positive, long-term learning outcomes (Newman et al., 2013; Rodd & Newman, 2009; Won Hur & Anderson, 2013) when serving as the main instructional strategy in STEM classrooms. Unfortunately, it also has been shown that these approaches often are cut or shortened because of the perceived need to use class time to provide knowledge transfer via lecture and overview of textbook material (Newman & Gullie, 2009). The flipped classroom strives to eliminate the classroom conflict between lecture and hands-on assignments by allowing students, via technology, to hear and review basic content knowledge outside the classroom and thus, to engage in active learning inside the classroom (Chirinian, 2012). This flipping of the classroom structure allows the instructors and the students time during class to focus on activities that cultivate creativity, critical thinking, discovery-based problem solving, and skills in communication (Chirinian, 2012; Loyens, Rikers, & Schmidt, 2008; Splan, Shea Porr, & Broyles, 2011).

The following case study provides an in-depth look at the implementation of a flipped classroom in a higher education STEM class, developed across three terms and replicated across two semesters. Video lectures, along with linked multimedia resources served as the major technological support for the transmittal of basic content and preliminary demonstrations.

CASE STUDY

Setting

As part of a large-scale Engineering Research Center's (ERC)[1] educational activities, faculty are investigating the role of alternative instructional approaches that support constructivist/constructionist learning in STEM fields. As one of the approaches under review, a flipped classroom is now being implemented in an undergraduate engineering course.

Electronic Instrumentation is a survey course serving students pursuing engineering and science majors other than electrical engineering. The course includes direct hands-on application of theoretical concepts; it typically consists of two sections of 50-70 students that meet twice a week (two hours each session). Originally, the course had a common two hour lecture offered each week with separate lab times staffed by teaching assistants. Beginning in 2010, video lectures and supporting materials covering important theories, concepts, and demonstrations related to the course were created and placed online for students to view on their own time in place of the in-class lecture; use of class time was refocused to emphasize hands-on, experiential practice of the course material using student-directed learning in groups of two and four. Under the new model, the instructor and teaching assistants (two to three per section) serve as facilitators within this hand-on learning time, and technology supplements of videos and linked resources are available to students to use outside to direct or support their in-class work.

Student feedback from initial evaluations of pilot use in Fall 2010, Spring 2011, and Fall 2011 assisted in material development. Additional video materials were developed in 2011-12 and all video lectures were made available on *YouTube* for greater accessibility. Student perceptions of student-directed group learning and video lectures and classroom observations of the implementation of group learning, collected during spring 2012 and fall 2012 semesters are summarized in this chapter.

Participants in the fully implemented case reported here include students (n=138) enrolled in the course during the spring and fall (replicate) semesters of 2012, as well as instructional staff. The students were primarily mechanical engineering majors in their third/fourth year of post-secondary study. Over three-quarters of the students were male (83%); three-quarters self-reported their ethnic origin as White. Scores on the Index of Learning Styles (Felder & Silverman, 1988) revealed that students in both the pilot (Spring 2012) and replicate (Fall 2012) semesters were primarily sensing (75%), visual (86%), and sequential (66%) learners, indicating that they preferred to learn using their physical senses (i.e., through hands-on experience and explicit instruction) via visual diagrams, demonstrations or modeling, pictures, graphs, etc. in a scaffolded, hierarchical (sequential) knowledge building manner.

The following data sources were used to collect information on the implementation of the flipped classroom:

- Pre and post-student surveys,
- Observations of in-class settings, and
- Student and faculty interviews.

Pre and post-course surveys of students enrolled in the flipped course were administered in the first and last week of each semester, respectively; items assessed students' overall perceptions of group learning, including the frequency of learning settings (e.g., how often students worked independently, with a partner or group of four for homework, studying, and during class time) and the primary decision-maker for regulating learning activities, as well as the use of online videos in place of in class lectures (e.g., frequency of use, perceptions of use, benefits and barriers toward use). Independent evaluator classroom observations took place throughout the semester to validate students' involvement in active learning within the collaborative group work setting including student-student interactions, teacher-student interactions, and group dynamics and the self-regulation processes of goal setting and progress monitoring. Interviews of students, independent of faculty input, were collected post-course to assess overall perceptions of the learning experience, especially the use of the flipped classroom and online videos as lectures.

Building a Flipped Classroom

As in all case studies, the instructional context and philosophy behind the change reveals important patterns. In this case, building a flipped classroom was a process, not an instantaneous endeavor. With the explosion in the population of engineering students in the last decade, in order to continue a philosophy of learning supported by the studio approach to learning (i.e., lectures and labs occur fluidly as one and is enhanced with the use of mobile studio technology) while also maintaining consistent and sufficient interaction and feedback with 150+ students during active learning, the instructor decided to flip the class. In 2009-10, while consulting and collaborating with colleagues at multiple universities, the instructor began the development and piloting of a series of video lectures on electronic engineering that would support flipping of specific curriculum units. Developed using *Jing* software, each revised unit represented key components of content and skills knowledge and were five minutes in length after development and editing; the development process took anywhere from 5-10 hours to record what was two hours of lecture material. After developing the video lectures, they and supporting materials were uploaded and available for use online via Blackboard's ™ Learning Management System and the course website as deemed appropriate by faculty and/or instructional staff in 2010. To assist in the transfer of knowledge to diverse groups of students, the videos were designed to meet the needs of multiple instructional uses (i.e., limited access, repeat access, sequenced access, and general availability) and student learning (i.e., more than one resource—multiple power points, online handouts of notes for each experiment, and online reading material from multiple websites).

As part of the initial piloting of the flipped classroom units, student use of the out-of-class video lectures was examined to determine students' actual access and sequencing of the videos and whether the videos met diverse learning preferences of students. Results indicated that the videos that delivered quiz review content were accessed, on average, more times (28 times, Fall 2010; 36 times, Spring 2011; 24, Fall 2011) than the videos explaining experiment related concepts (20 times, Fall 2010; 29 times, Spring 2011; 10

times, Fall 2011) across the three semesters. These uses suggested that the videos that covered course content, which was perceived as directly relevant to assessment, were valued more by students than were the videos that covered the content pertinent to in-class experiments and related activities. Student interviews confirmed student perceptions of using the flipped lecture format for concept review and understanding in framing and rehearsing information (e.g., "I used videos that focused on example problems to prepare for our quizzes and tests," "[I use online lectures to] go over sample exam problems," and "when studying for exams, these videos were a perfect way to quickly and efficiently review the most important topics expected on the exam").

As the flipped classroom was further implemented, initial student feedback also identified specific barriers to accessing the online video resources that reflected student assumption that information would be available independently, immediately, and non-sequentially. For instance, students noted one significant barrier was the need to download each video individually; the process was *time consuming* and *frustrating* (Connor, Berry, Chouikha, Newman, Deyoe, Anaya, & Brubaker, 2011). Additional barriers included difficulty accessing specific parts of the video to get to information students needed or wanted (Connor, et al., 2011). In addition, students reported redundancy in using continuity lead-ins and did not perceive a need for it. As a result of this feedback, the videos were uploaded on *YouTube,* a format with which most students had prior experience and greater comfort level in using, and functions were established that allowed for easier access where videos could be watched individually, in segments, or in sequence as one long lecture. New videos were developed that addressed topics in a more focused manner that connected with content across assignments. The instructor also added search tags within the *YouTube* channel to assist in finding information by topic. In addition, the course instructor restructured the course webpage to provide even more of a user-friendly format for students and has developed a continuous pattern of updating material for the students.

Because students in this class were not electrical engineering majors, typically background knowledge and interest waned in learning the material and students needed external support. As a result, through collaboration with faculty at multiple universities who teach subjects in electrical engineering, learning strategies, grounded in Bloom's Taxonomy, were developed and implemented that would allow students to achieve and addressed topics at three levels: basic ideal theory, simulations, and hands-on experiments, and subsequently develop a useful systems model combining lessons learned at each level. Guided note supplements were developed to provide additional information on assignments, specific documents and videos were linked on the website to show students the process involved in conducting higher level thinking in engineering.

Methods for monitoring use and support for self-directed learning also were addressed. In terms of the active learning aspect of the flipped classroom, original verification of student learning occurred as part of a check-off procedure wherein the teaching assistant (TA) or the instructor signed off on completed assignments. This type of assessment, however, decreased the value of learning to learn, the purpose of implementing the flipped classroom. The original checklist assessment was enhanced by implementing a rubric for TAs and the instructor to follow when checking for understanding. The rubric now requires students to discuss their work by answering specific questions that gauge the students' level of learning; these rubrics are provided ahead of time, so students know what to expect. The instructor also has implemented a questioning aspect based on the teaching strategy of "Think, Pair, Share" (i.e., students think about and come up with an answer to a question, pair with a partner and share their thoughts) into the labs to facilitate their thinking on important concepts while they worked on assignments, and also served as a form of formative assessment. Using this approach, in the beginning of class, students work together in groups of four to answer questions on the material from the lab assignments and video lectures. This questioning process helps check for student understanding and allows the instructor to provide additional information on the topics and have a brief discussion on the topics during a 3-5 minute lecture halfway through class time. These strategies also now give the students the in-class time they perceived was important to have in addition to the video lectures for their understanding of concepts.

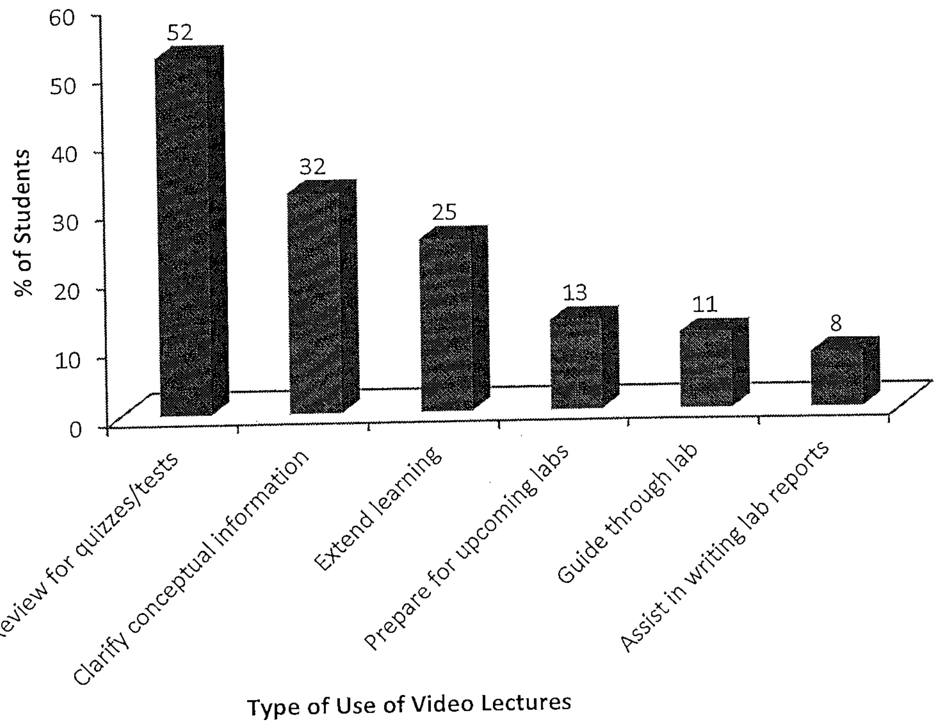
The Role of Technology: An Aid for Knowledge Rehearsal and Enhancement

As noted previously, the majority of students evidenced learning styles that were sensing, visual, and sequential. As a result, during development, the format of the flipped lectures was aligned with students' learning preferences to include observing and interpreting visual and graphic representations of information rather than interpretation of printed text about concepts and ideas. In addition, the flipped online lectures were delivered using a combination of voice, text, and graphical representations of course content, appropriate for an overall preference for visual learning.

When asked how they used these videos and other resources, students indicated the online video lectures were accessed primarily for extension or rehearsal of knowledge in the content area (See Figure 1). When asked for specific examples, they noted "It [video lectures] was good for studying," "It [video lectures] allowed for reviewing a lecture multiple times," and "Clarified concepts before quizzes." Students reported that they occasionally watched the online videos prior to the corresponding lab as a way to prepare for the assignment, but most viewed them at a later date to rehearse or focus learning. In general, students comments reflected the basic principles behind the flipped classroom—external access to basic content allowed for increased active engagement in class (e.g., "[Watching the videos provided them with] more time to focus on experiments during lab time," and "Class time was more productive"). Most reported using the video lectures "post-hoc" to consolidate the experiences they had during the hands-on lab and to place these experiences in a theoretical context, that is, most importantly, they flipped knowledge acquisition in a constructivist mode by first experiencing the learning in class and then framing the learned material in theory via the video lectures outside of class.

Participating in and valuing a flipped classroom did appear to be a learned process for these students, reflecting a need to establish a methodological comfort level. A majority of the students enrolled in the course did not perceive that the use of online videos made the course any more difficult than a traditional lecture-based course. Over time, as instructor experience increased, student preferences for lectures also shifted. At the end of the Spring 2012 pilot course, most students still reported a preference to attend a formal lecture rather than watch online videos; however, students in the Fall 2012 replication class reported a decrease in their preference in attending a weekly lecture, wanting instead to use online videos. These findings suggest that as replicated use occurs by a faculty member, students demonstrate an emerging acceptance of the flipped classroom approach. This may be related to instructor comfort level with the use of a flipped approach as well as students' prior experience and their "word-of-mouth" expectations of the classroom. However it should be noted that, after the second full replication while most now wanted online videos, over half (60%) of the students reported that they were still not comfortable using the video lectures for learning (see Table 1). There may be several reasons for this continual hesitance. When queried more specifically, many students reported an overall low competency level in actual use of the videos for learning (i.e., the process of selecting

Figure 1. Frequency of online video use
**Numbers represent percentages of participants who responded "often"/"most of the time."*



and running videos and deciding when to close); they did not know how to transfer or convey this new information because the tool was not part of their learning repertoire. Their responses to how, if ever, they had used video learning pedagogy in other courses, indicated prior use related to didactic learning approaches (e.g., for rehearsal, supplemental or enhanced learning goals), not for the primary mode of transferring new content (e.g., constructivist acquisition of knowledge). These prior experiences appear to have served as a barrier to use of videos in a constructivist, flipped approach.

As did their prior use, perceptions of the role of the current flipped classroom in promoting student-centered learning and providing increased opportunity for direct interaction with the instructor varied across students. One-third (33%) of the students strongly supported the process noting that the use of the video lectures enabled self-directed learning (e.g., "I could choose what I needed to review and when," "Allowed explanation multiple times," "watch[ed] at my own pace/schedule," and "I could pause the videos and listen again"). The majority of students (79%), however, did not perceive use of the online lectures to allow for increased interaction with the instructor. They wanted the comfort of lectures and the possibility of direct questioning of instructors during transferal of facts along with the questioning available during the hands-on experience. The need to verify learning via questioning, usually provided through instructor contact during lectures, was specifically noted (e.g., "I couldn't ask questions or get clarification right away," "Lack of interaction with professor [during videos]"). This need for more ability to question may be a result of prior learning experiences or increased student expectations in the new approach; as more opportunities to question were provided, more

*Table 1. Perceptions of online video usage**

Statement	% Post (n=138)
I prefer a formal weekly lecture instead of online videos.	66
Taking a course using online videos was more difficult than taking a traditional lecture-based course.	40
I (will be) was comfortable when using online videos for learning.	38
Taking a course with online videos allowed me to self- direct my learning.	33
Taking a course with online videos provided more opportunity to learn content during class/lab.	20
Taking a course with online videos allowed for increased interaction with the instructor during class/lab.	19
I am the type that learns well with online videos.	18
The skills I developed through online video resources are valued by companies I am likely to work for.	16

were sought. Observations documented that the instructor and the TAs were present during the scheduled hands-on practice time and were fully engaged and effective in using the practice time in class to address student queries or comments whereas in the past lecture class/lab arrangement there was less direct questioning time.

The Role of Active Learning

Despite students' mixed perceptions of the process, positive outcomes related to hands-on collaborative learning via the use of a technology supported flipped classroom were supported. Students' self-reported learning responses and external observations confirmed the presence of a student-centered, collaborative active learning environment within the flipped classroom. As demonstrated in Table 2, students predominantly worked in dyads or teams of four (by merging dyads). Almost all (92%) of the students reported that they regularly worked with a dyad partner, reinforcing skills related to sharing and communicating information needed to complete a task. In addition, almost half the students experienced the additional collaboration skills needed for larger team efforts; 44% had at least one experience of working with two or more partners, and 37% experienced multi-team interactions when their dyad merged with other teams to complete tasks. Data indicated that students' regulation of learning outside of the classroom remained primarily self-directed and autonomous; 70% of students worked independently on "homework" that now included watching videos and accessing online resources. However, it is noteworthy that 30% of the students did move their collaborative partnership outside the classroom and shared "homework" tasks. This extension to outside preparation was primarily contained within the dyad partnership. Some portions of this collaborative effort also continued into preparation for assessment tasks; 26% of the students maintained their dyad collaboration even when preparing for tests and quizzes.

The freedom to redesign the physical classroom when moving to a flipped classroom also is important to note. Class observations and student responses revealed that the lab "looked" like a professional setting with problem-solving teams working on assigned tasks or problems. This ability to mock up or model professional roles helps to establish professional values needed when in the work place. The majority of the students indicated their collaborative team predominantly decided together on the specific activities required to regulate learning, including goal development, division of tasks, completion of lab write-ups,

etc.; all of these skills are needed for workplace problem-solving (See Table 3). Students were aware of the value of this part of the learning process, noting that the new structure enabled them to collaborate and share ideas as though in a real professional setting. The one activity, however, that students did not want to incorporate was the instructor's role in determining the content about which students were to learn. Most acknowledged this as part of the instructor's "expertise" role, but many also noted that this directive also resembled a professional setting where a manager or executive would pose problems that employees would have to solve in a team approach.

Once again, instructor familiarity and students' expectations may play a role in task division. When the approach was replicated in the fall term, an increase was found in students' responses regarding the amount to which the team divided up tasks (72% Spring 2012 increased to 80% Fall 2012), documented their progress (51% increased to 66%), and completed lab write-ups (increased from 83% to 86%). When specifically queried on their perceptions of group learning, the majority of students in the replication study noted their preference for group learning, as opposed to instructor-directed learning, as well as a higher level of comfort when working in a group; a skill again noted by the students to be of value for their future professions. These constructivist characteristics of learning, and their emerging duplication outside the classroom into their homework setting, further confirms the increased value students learned to place on active, student-centered knowledge generating experiences provided by the flipped classroom.

The Role of Prior Experience

Previous research has shown that prior experience is a concomitant variable that influences student outcomes relating to STEM learning and should be considered when designing and developing new initiatives in pedagogy (Newman, Clure, Deyoe, & Connor, 2012; Newman, Clure, Deyoe, & Connor, 2013). As briefly discussed earlier in the chapter, similar findings were found within the flipped classroom setting. Following is a more in-depth discussion of this important variable. Those students with prior experience in participating in a flipped classroom environment were more comfortable and appreciative of the opportunity to learn content via in-class constructivist activities. They also perceived that the flipped classroom allowed for more interaction with the instructor. There was, however, no difference in the use of online video lectures and other resources for learning between students who had prior experience with a flipped classroom and those who did not; both sets of students indicated they used the online videos to review and to clarify conceptual information after the constructivist experience.

Important variations in their own perceptions of learning via a flipped classroom approach were noted when differentiating for prior experience with the process, but the difference varied by the complexity of learning goals. Although all responses were relatively high, those students without prior flipped classroom experience tended to report even higher levels of preparation in content specific domains than did those with prior experience in constructing knowledge. For instance, in terms of course specific knowledge, those with no prior experience reported higher or better preparation than those with prior experience in: 1) using and applying specific math, science, and engineering knowledge to their assigned tasks; 2) designing and conducting specific experiments and analyzing and interpreting data; and 3) designing specific components on assignments and solving specific problems.

Students with prior flipped classroom experience, however, noted much higher preparation in skills reflective of more complex engineering ability and professionalism. Those with prior experience viewed themselves as more prepared than did those with no prior experience in being able to:

- Formulate and then solve general engineering problems;
- Work on single disciplinary and multi-disciplinary teams;
- Understand ethical responsibilities and address global and societal issues; and
- Take into account cultural values and contemporary issues in their professional work.

Students with no prior experience in flipped classrooms using constructivist approaches were significantly lower in their perception of being able to perform these types of tasks.

As noted earlier, although all students noted positive responses in preparedness of specific tasks and those with prior experience had more confidence in conducting generalized tasks, all students maintained a preference for some form of a formal weekly lecture. They appeared to value the practical applications and acquisition of skills, but still wanted some type of "expert face-to-face" transfer of knowledge that would validate the information. Students' predilection for concept learning via formal lecture suggests that this new approach, in which students collaboratively build knowledge, takes time to change students' predisposed mindset on how to learn.

Benefits, Limitations, and Solutions for Flipped Learning

Stated advantages of the online video lectures corresponded to students' reported use. The greatest and most frequently noted benefit was unrestricted access to the video lectures and linked resources for review, enhanced learning, and framing of knowledge (see Table 4). When specifically queried, student provided explicit benefits related to the ability to access the lectures at any time that reflected the promotion of knowledge rehearsal, greater allowance of hands-on practice of concepts, and the facilitation of self-paced learning (e.g., "I

Table 4. Benefits and limitations of video lectures

	Student Responses
Benefits	• Helped when studying for tests/quizzes • Unlimited access/could re-watch • Work at own pace • Provided more class/practice time • Extended the topic
Limitations	• Lost motivation/attention • No way to ask questions • No feedback from professor • Took more time
Suggestions	• Make videos more accessible • Use only lectures • Provide lectures and videos • Make videos more exciting/shorter/ more examples • Make videos mandatory

was more prepared for lab," "made it easier to study for tests," "allows flexibility in scheduling my time," "it allowed me to learn at my own pace," "more time to focus on experiments during lab time," and "clarified concepts for me before quizzes").

As noted previously, although many students had prior experience with using video lectures, they continued to express limitations with student-centered, self-directed learning and learning promoted via the flipped classroom. The most frequent limitation noted was a reported decreased interaction with the instructor (i.e., less than they had in traditional lecture settings); they noted they "Would rather have personal interaction with the professor," "couldn't ask questions [during video lectures]," and "[spent] lots of time involved outside of class, with less involvement from the professor [during video lecture]." This may reflect an expectation of instructional delivery found in the traditional teacher-directed classrooms in the STEM domain promoted by previous experiences. As noted earlier however, students actually had more time for direct questions, but the questions now focused on direct practice and application.

The perceived limitation of less interaction with the instructor and/or lack of validation of expert transfer was further documented when students were queried as to what changes they would make to the flipped classroom. Responses included, "Provide in-class lectures in addition to the video lectures," "Make it one lecture and one video" and "I would use them as supplements, not as the base for learning." Students also noted specific ways to streamline their ability to access the resources that reflected their need for sequence (e.g., "Make the titles of the videos logical in such a way that they are easy to search for and share while on YouTube," and "Organize chronologically instead of alphabetically"). These responses appeared to reflect students' prior experience with self-directed learning and their technological ease of use in utilizing *YouTube*. Those with more experience were more comfortable and better able to flip their learning process and access to information. Several students commented that they did not have to spend as much time studying the formal content (e.g., the videos and resources) because of the active, collaborative learning the class time provided; they noted that learning content while "doing" and using the resources to help them understand the "why" of physically working with electronic components and they rehearsed the "how and why" content via videos. One student stated,

When I was building a circuit, I didn't really have to study because I had learned by building and could see what each circuit did.

Several students indicated that the class time was helpful in motivating them to learn because they were able to learn concepts and theories in concrete, practical ways (e.g., "[Use of hands-on materials was] more motivating because it is [a] more practical application to learn," "[Lab] allowed me to see it rather than read it on a page," and "[lab work helped me in] comparing [electrical] components to real life").

Several students acknowledged the combined limitations and benefits of both methods and were explicit in expressing a need for a more blended approach to instruction, suggesting an integration of the "flipped classroom" approach and direct instruction techniques until they adjusted to the new learning techniques. Instructors and teaching assistants perceived part of the students' lack of comfort to relate to the use of increased student self-monitoring and self-structured learning; students found it easier and more in their comfort zone if they had a more faculty-directed approach (e.g., making the online lectures a requirement and monitoring the students' use of the tools with a brief 10-minute review period at the beginning of each lab and/or including two to three questions for students to answer as they watch the videos and then bring to lab for brief discussion). Use of a blended approach was supported by student comments across semesters indicating that lack of guidance on when to use the videos as well as lack of instructor monitoring of video use were drawbacks to using video lectures outside of class for learning. Many students did not want to be responsible for monitoring their own learning time and mode. They wanted specific directions reflecting requirements of use (e.g., "It was very difficult to figure out when to watch specific videos. Schedule them and group them into folders, so we know what to watch," or "Make it required, as I have not watched all the videos, which could hinder my grade"). Faculty noted that although this instilled the importance of the online lectures to the learning process, it would not support growth of students' self-direction and the learning of professional responsibility. Again, it should be noted that what might be a limitation for those with no prior experience was frequently a benefit for those with experience.

FUTURE RESEARCH IMPLICATIONS

The implementation of the flipped classroom reveals several implications for further research. Although this type of learning is becoming increasingly commonplace as a means of meeting the needs of today's students, most participants are still used to traditional methods of learning and may offer some resistance to instruction provided this way, particularly in STEM areas where underlying content is expected to be rule and procedure-based. Future research should focus on the impact of implementing the flipped classroom as a "continuum" process, ranging from didactic-led to a blended approach to a flipped classroom-only setting to determine if a slower transition can ease student anxiety toward learning via these new methods. Longitudinal research in this area may be beneficial for determining if the same issues occur when students have been introduced to flipped classroom learning at younger ages. Future studies also should focus on the delivery method of the content, alternate types and roles of technology, and differences in outcomes based on the technology and methods used.

Further research should focus on the impact of flipped classrooms on individual learning, and provide a foundation for more research on group variables. The active experimentation and real world experiences of the flipped classroom's in-class setting provide the basis of learning through constructionism and constructivism (Kafai & Resnick, 1996). Using flipped classrooms as the instructional model to support constructivist learning means that learners are responsible for their own learning, thus strengthening self-regulatory skills needed in professional settings (Loyens et al., 2008). In addition, this student-centered learning is often conducted in collaborative student groups. Inquiry is needed on both the process and products related to collaborative learning embedded within flipped instruction.

CONCLUSION

The use of a technology supported flipped classroom is an alternative way to engage students in active learning that will promote critical thinking and problem solving skills necessary for success in the 21st century. In this chapter, we focus on one type of flipped classroom, used in a higher education STEM class, developed across three terms and replicated across two semesters to document benefits and limitations to the approach, the role of the video lectures in the approach, and the process of active learning within the classroom.

Both students and faculty perceived benefits to this model. Students viewed the online video lectures as a resource that reinforced and expanded their conceptual understanding of the course material, but did not see the videos as a validated way of transferring new content. They still wanted access to the instructor for direct transfer of basic content and skills. Although in reality, the approach allowed them more access to instructor expertise, there appeared to be a need for continued confirmation of concept understanding that they only perceived as being met if it was a face-to-face transfer. Many students noted that unrestricted access to the online lectures facilitated knowledge rehearsal, increased hands-on practice by freeing up class time, and helped to develop self-regulated learning. Students found the use of the online video lectures to be most helpful when studying for quizzes and tests, particularly noting the capability of re-watching the videos and reconstructing what they wanted/needed to cover.

Half of the students indicated they did not find learning from online lectures more difficult than learning from traditional lectures; however, when asked about barriers to learning, the majority of students were consistent with their preference for traditional lectures, and were not comfortable using the online lectures as their primary forum for what they perceived to be the transfer of content. Other specific limitations or concerns to using the online videos included the delivery of information and the structure of the listing of the videos on *YouTube*. Comments from many students suggested that blending the flipped and traditional classroom approach might be beneficial in providing some of the structure with which they are familiar while continuing to promote and transition to self-regulated learning in the flipped classroom. These issues increase the importance of the role of technology in supporting and forming a blended transitional flipped classroom.

Despite the continuation of the need for the traditional affirmation of expertise, the students indicated the value of gaining experience in collaborative and problem-solving skills that are to be expected when they are on-the-job. The value of this collaborative hands-on approach offered by a flipped classroom was further verified as students gained confidence in their ability to function as a team and to use team monitoring of progress. Approximately one-third of the students transferred this outside the required flipped setting and continued to use these skills elsewhere. The ability of technology to provide flexibility in synchronous and asynchronous instructor/student interaction could be harnessed to address these communication concerns. Additional multimedia uses including just-in-time audio and video recordings of demonstrations and group work could be developed.

Student expectations of and prior experience with what is considered an appropriate instructional setting also appears to play a role in the acceptance of flipped classrooms. As noted, during the second replication, students, even though new to the class, were more accepting of the approach. This may be related to instructor comfort level, but also might indicate a higher level of student experience. As the use of flipped classrooms expand in secondary education settings, and as more use is experienced in post-secondary education settings, students' comfort levels and prior experience will shift. These shifts may be further related to changes in motivation, expectation, and students' learning style preferences. As the use of flipped classrooms increases, as student and faculty expectation and comfort levels are met, it can be expected that even greater evidence of constructivist learning will be evidenced.

KEY TERMS AND DEFINITIONS

Active Experimentation: Application of concepts in real world contexts.

Asynchronous Communication: One-sided communication where one party sends a message to another; electronically this can include discussion boards, e-mail, streaming video or podcasts, etc.

Constructionism: The idea that effective learning occurs when students actively build concrete artifacts that applies to the content; stems from experiential learning.

Constructivist Learning: Learning theory that refers to the idea that students construct knowledge through their own experiences.

Flipped Classroom: Classroom that uses in-class time for concept application or "homework" and time outside of class to learn the concepts through electronic lectures, PowerPoint slides, podcasts, etc.

Self-Directed Learning: When individual learners are motivated to take on decisions related to their own learning.

Student-Centered Learning: A form of learning where students are responsible for their learning; the instructor is a facilitator.

Synchronous Communication: Interaction between parties that occurs in the present time.

Chapter 3
Blended Learning to Support Alternative Teacher Certification

ABSTRACT

This chapter reviews literature on the use of e-learning to complement and extend preservice and inservice teacher education. It also provides an in depth example of the design and implementation of blended learning for supporting alternative teacher certification. In light of the example, research findings are summarized. The second part of the chapter provides a discussion on the following strategies that led to the successful use of blended learning in alternative teacher certification and explains how applying them can contribute to effective uses of blended learning in other settings: a) leveraging a network of partners, b) designing blended learning to address needs of multiple learners and organizational entities, c) balancing standardization and customization, and d) conducting evaluation and engaging in continuous improvement.

INTRODUCTION

The educational system has been described as disjointed and consisting of loosely coupled systems that have little impact and relation to one another (Meyer & Rowan, 1977; Weick, 1976). However, in recent years, online environments and embedded technologies have served as resources for aligning individuals who work in various capacities across educational systems. Capitalizing on affordances of emerging technologies, individuals and groups can convene in shared spaces for collective work to support student learning (Greenhow, Robelia, & Hughes, 2009), facilitate data-driven decision-making (Kowalski, Lasley, & Mahoney, 2007), enable knowledge-building communities (Scardamalia & Bereiter, 1991), and support teacher learning (Zhang, 2009). Such online learning

DOI: 10.4018/978-1-4666-8246-7.ch003

environments are opportunities for tightening linkages across systems. This work is beginning to take place in preservice and inservice teacher education, where research suggests that e-learning can be effectively employed to meet a variety of learning and practical needs (Fishman, Marx, Best, & Tal, 2003; Whitehouse, Breit, McCloskey, Ketelhut, & Dede, 2006).

Blended learning that combines face-to-face instruction and e-learning is increasingly being used in teacher education for training, induction, and professional development (Barab, MaKinster, & Scheckler, 2004; Dukes & Jones, 2007; Whitehouse, et al., 2006). Blended learning can be implemented in a variety of ways, such as e-learning being supplemental to traditional face-to-face instruction, e-learning replacing face-to-face activities, or as traditional and online offerings that are available to learners on demand (Stacey & Gerbic, 2009).

The objective of this chapter is to explain how blended learning has been used to support alternative teacher certification, which is an emerging aspect of teacher preparation. The chapter summarizes how blended learning was employed in this effort and relays results of research studies. The chapter also describes strategies that enabled the successful design, development, implementation, and continuous improvement of blended learning in this capacity. It also highlights potential directions for future research.

BACKGROUND

Alternative Teacher Certification

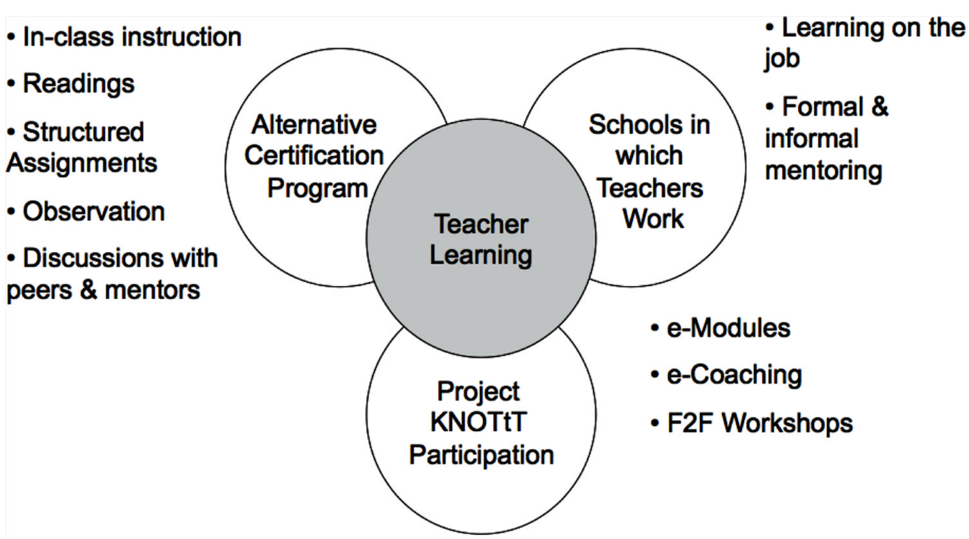
Alternative certification is one aspect of teacher preparation where blended learning can be used to support new teachers due to a shortened teacher preparation time and concerns that have been raised about teacher mentoring programs. Over the past 25 years approximately half a million teachers have been credentialed through alternative or "nontraditional" state-approved programs across the 50 U.S. states and the District of Columbia. The expansion of alternative teacher preparation that began in the late 1980s in New Jersey, California, and Texas has continued into the 21st century. Currently, about 600 program providers annually certify about 62,000 teachers through state-defined alternative routes to teacher certification (Feistritzer, 2009). School districts, educational service agencies, universities, four-year colleges, two-year community colleges, for-profit and nonprofit organizations, and partnerships of these entities deliver these programs. Also included are national programs like Troops to Teachers, which serves military personnel moving into teaching positions, and Teach for America, which focuses on new college graduates who did not major in education (Boyd et al., 2008; Darling-Hammond, Holtzman, Gatlin, & Heilig, 2005; Feistritzer & Haar, 2008; Haberman, 2006; Rosenberg & Sindelar, 2005). Combined, these alternative programs are designed to prepare teachers who have the knowledge, dispositions, and self-efficacy to effectively teach students while addressing staffing needs (Chin & Young, 2007; Clewell & Vilegas, 1999; Feistritzer, 2009; Gimbert, Cristol, & Sene, 2007; Guarnio, Santibanez, & Daley, 2006).

Mentoring is a form of professional development that is often provided to beginning teachers to help address knowledge needs, influence teachers' perspectives (U.S. Department of Education, 2002), and support teacher retention (Chin & Young, 2007; Feiman-Nemser, 1996; Smith & Ingersoll, 2004). Despite the potential for job-embedded mentoring, research suggests that teachers who enter the profession through alternative routes often report feeling isolated, overwhelmed, and unprepared for the realities of teaching (Carter & Keiler, 2009; Darling-Hammond, Chung, & Frelow, 2002; Gratch, 1998; Isaacs et al., 2007). In particular, teachers have reported a need for additional help with classroom management and motivating students, making effective use of limited instructional planning time, differentiating instruction, and learning to work with minority student populations (Bradbury & Koballa, 2007; Chesley, Wood, & Zepeda, 1997; King & Bey, 1995; Utsumi & Kizu, 2006). E-learning can potentially supplement alternative certification and school district mentoring programs by providing teachers access to organizational outsiders who can help them develop knowledge, skills and self-efficacy.

Project KNOTtT

Project KNOTtT is a multi-state initiative for building capacity among universities, school districts, state departments of education, and non-profit organizations to support the preparation of alternatively certified teachers in Kansas, Nevada, Ohio and Texas. Project KNOTtT was funded in 2007 by a five-year Transition to Teaching grant through the U.S. Department of Education's Office of Innovation and Improvement. The project was designed to supplement preservice training and district support that teachers trained through alternative routes receive. KNOTtT partners work independently and collectively to recruit, prepare, support, and retain teachers of record in high need, hard-to-staff school districts. Project KNOTtT aims to support the ongoing work of alternative certification programs, as well as teachers who enter the teaching profession through alternative routes. Drawing on the communities of practice (CoP) framework (Wenger, 1998), KNOTtT can be described as a CoP that is informed by and that intersects with other communities. Teachers who participate in Project KNOTtT have opportunities to learn across a number of contexts: (1) the alternative certification programs in which they enroll, (2) the schools in which they teach, and (3) participation in Project KNOTtT (Figure 1). Through enrollment in an alternative certification program, teachers receive in-class instruction, are assigned readings about teaching and learning, are directed to complete structured assignments, are granted opportunities to observe instruction, and interact with and learn from fellow interns and program mentors. Upon successful completion of an alternative certification program, teachers continue learning on the job through professional learning experiences, reflection, and formal and informal mentoring.

Figure 1. Contexts of teacher learning in relation to project KNOTtT participation



Project KNOTtT Blended Learning Environment

One of several mechanisms Project KNOTtT uses to support local partners' teacher preparation efforts is the KNOTtT blended learning environment, which combines elements of traditional face-to-face instruction and online instruction across a variety of contexts. These contexts include face-to-face training sessions conducted during on-site visits, face-to-face national meetings that provide a venue for KNOTtT partners to collaboratively plan and improve program quality, and the KNOTtT website. The KNOTtT website is an online learning community that provides a space for teacher candidate learning and collaboration among KNOTtT partners. Through program participation in Project KNOTtT, alternatively certified teachers receive instruction in the areas of mathematics, science, social studies, English/language arts, foreign language, English as a second language, and special education. The intended learning outcomes are for teachers to acquire the knowledge and skills to pass their state's teacher certification exams, to increase teacher self-efficacy to teach in complex school settings, and to contribute to the capacity of alternative certification programs to prepare teachers to teach in high need hard-to-staff schools. Blended learning is distributed across the following components:

- **Face-to-Face Workshops:** Face-to-face workshops on content-specific instruction or general teaching strategies are conducted during on-site visits with partnering alternative certification programs one to three times per year.
- **E-Modules:** The Project KNOTtT website hosts e-Modules, which provide teachers programmed instruction on content and skills that will be covered on their state certification exams.
- **E-Coaching:** Teachers also visit the website to attend online synchronous e-Coaching sessions that are offered two to three times a month. E-coaching is coaching that is conducted using telecommunication technologies and devices such as telephones, chat rooms, instant messaging, and Bluetooth earpieces (Costello-Dougherty, 2008; Rock et al., 2009; Rossett & Marino, 2005). Benefits of e-Coaching include the ability for one coach to support multiple individuals while also addressing practical constraints related to location, scheduling, and costs. During Project KNOTtT's e-Coaching sessions, coaches introduce a topic and model teaching within the content area. Coaches pose questions for the participating teachers to attempt to solve on their own. Coaches also use the poll feature of the video-conferencing environment to assess teachers' understanding and provide real-time feedback. Teachers who are not able to attend a group e-Coaching session or who desire to review material covered during the session can visit the Project KNOTtT website to view archived sessions.

Project KNOTtT Blended Learning Research

Project KNOTtT evaluation and research studies suggest that the blended learning environment effectively supported teacher learning and helped build alternative certification program capacity. In response to a 2010 annual survey, 86% of teachers reported that e-Coaching was moderately to very moderately responsive to their needs as new teachers, and 88% reported that the e-Coaches were moderately to very helpful. Previous research suggests that a blended learning environment can be just as effective as a traditional training program in preparing teachers to pass state licensure exams

(Gimbert, Moore, & Sahin, 2008), that online professional development can have a positive impact on teacher knowledge (O'Dwyer et al., 2010), and that online courses can promote contextual learning opportunities for teachers (Mackey, 2009).

Two studies were conducted to examine the relationship between Project KNOTtT blended learning participation and teachers' gain in self-efficacy over the course of their first year of teaching. Self-efficacy was selected as a focus of inquiry because efficacious teachers believe in their capacity to organize and execute successful teaching tasks, even in highly complex settings. Additionally, teacher self-efficacy has been described as one of the most powerful teacher attributes (Guskey, 1987; Knoblauch & Woolfolk Hoy, 2008), and it has been linked to teacher retention (Glickman & Tamashiro, 1982). A pilot study conducted during the 2009-10 school year revealed that teachers who attended at least six e-Coaching sessions reported a gain in self-efficacy. Furthermore, teachers who appeared to benefit the most from using e-Coaching were those who began the school year with lower levels of self-efficacy than their peers (Anthony, Gimbert, Fultz, & Parker, 2011).

A second study was conducted that combined data from two cohorts of alternatively certified teachers, one that began teaching in autumn 2009 and another that began in 2010 (Anthony, Gimbert, & Fultz, 2013). Teachers were provided access to professional development through Project KNOTtT blended learning, yet had varying levels of attendance in the e-Coaching online component. One group attended six or more sessions, another group attended one to five sessions, and a third group chose not to attend although their alternative certification program required attendance. Again, results showed that teachers who attended six or more e-Coaching sessions began the school year with lower levels of self-efficacy than those who attended five or fewer e-Coaching sessions. Furthermore, teachers who attended six or more e-Coaching sessions reported significant gains in self-efficacy over their first year of teaching, whereas teachers who attended five or fewer sessions did not report significant gains. Open-ended survey responses revealed that teachers who attended a greater number of e-Coaching sessions provided more positive comments about how the online component supported their efforts to grow professionally. They described the participation as complementary to their other professional learning experiences such as their alternative certification program training and support they received from a teacher mentor. However, teachers who attended few sessions described the online component as a good way to "brush up" on the content and to prepare for the exam. Teachers also voiced concern about the time commitment required to participate. They reported that they were already overwhelmed with demands of working as a beginning teacher and that the online portion was an extra burden. Some teachers even reported that they preferred the e-Modules to e-Coaching because they could quickly go online with minimal disruption to their schedules and avoid interaction with others.

Combined, study findings suggest that simply requiring teachers to attend e-Coaching did not translate to teachers' equal e-Coaching use or similar self-efficacy outcomes. Although teachers who did not pass their certification exam were required by their alternative certification program to attend e-Coaching, not all teachers complied with this requirement. Thus, teachers had varying levels of e-Coaching attendance. Teachers who participated in e-Coaching the most began the school year with lower levels of self-efficacy than teachers who attended zero to five sessions. Findings suggest that programmatic efforts to use blended learning to support teachers should be accompanied with policies and incentives that encourage use, along with scheduling adjustments that reserve time for teachers' frequent and meaningful use of the online component of blended learning.

BLENDED LEARNING IN TEACHER EDUCATION

Challenge

Despite some evidence that e-learning can complement face-to-face instruction to support teacher learning, ever-expanding options for the technologies that can be integrated into teacher education, along with an increase in options of blended learning models, present a challenge for decision makers. Given the many forms blended learning can take, it is difficult to determine whether an instance of blended learning that was effective in one setting will also be effective in another. Thus, research is needed that not only demonstrates effectiveness, but studies that also provide insights into design and implementation considerations.

Given the challenge of designing blended learning experiences for increasingly diverse structures of teacher education, while at the same time tools and models for blended learning continue to expand, those charged with making decisions about blended learning may find themselves in a position where the research cycle has not kept pace with such rapid growth. Because program planners may not always be able to draw on research to inform their decisions, they must draw on conceptual understandings of design and institutional support for program implementation. The sections that follow describe success strategies that led to the effective use of blended learning in the context of Project KNOTtT. Such strategies can be applied to the use of blended learning in other teacher education settings.

Success Strategies

Network of Partners: The work of designing, developing, implementing, evaluating, and continuously improving blended learning was not left to the responsibility of an instructor attempting to manage all of this on his or her own. Instead, this work was planned and conducted by a network of institutions that were a part of Project KNOTtT and that together supported the successful use of blended learning for beginning teachers.

Members of the core Project KNOTtT team at The Ohio State University included the project director, senior project manager, IT specialists, researchers, and project staff. The core project team worked with an instructional design firm and hired subject matter experts to help design the e-Modules. E-Coaches also planned and conducted e-Coaching sessions. The core team trained program partners and teachers on using the KNOTtT learning management system and worked with researchers to evaluate the use and effectiveness of blended learning to support teachers.

Alternative certification program coordinators gave input on teacher candidates' particular needs, which contributed to the initial design of e-Modules, e-Coaching, and occasional face-to-face sessions planned and led by the KNOTtT core project team. Program sites were well positioned to monitor teachers' e-Coaching attendance, and depending on state requirements and timing of teachers' certification exams, to encourage teachers still needing to pass exams to participate in e-Coaching.

Each partner site contributed unique knowledge and expertise to the development of the Project KNOTtT website, which supported all partners. In the absence of working with partners, the core Project KNOTtT team may have succeeded in designing the online components of blended learning; however, the partners were integral to ensuring buy-in at the local level and integrating the online components with face-to-face aspects of their teacher training and mentoring programs.

The project manager from the Project KNOTtT core team convened monthly meetings with alternative certification program coordinators and e-Coaches to debrief on how upcoming sessions could be tailored to meet the specific needs of teachers at local sites. During e-Coaching sessions with teachers, the KNOTtT project manager or an alternative certification program coordinator assisted the e-Coach during coaching sessions, helping to monitor teachers' questions and ensure that the session ran smoothly. Additionally, a series of annual meetings were held with members of the KNOTtT core team and program partners to ensure communication and evaluation.

Instructional Design for Multiple Learners and Entities: A rigorous instructional design process informed Project KNOTtT's attempt at blended learning. Blended learning was designed to support teachers as learners to increase their content knowledge and their sense of self-efficacy as well as to support alternative certification programs. The coordinated efforts of the Project KNOTtT core team and partners enabled the design of the blended learning environment to extend beyond e-learning technologies to also attend to the broader social structures of the various partners.

The learning environment was designed to meet the needs of multiple groups of teacher learners: (a) future teacher interns who must pass state licensure exams in order to enroll in alternative certification, (b) teacher interns who successfully completed alternative certification program training, yet still needed to pass state certification exams, and (c) novice inservice teachers who earned certification and could benefit from additional opportunities to learn pedagogical content knowledge and classroom management strategies.

One way the KNOTtT core team managed the scope of the project was to work with designers to incrementally scale up the online components. This allowed time for corrections and opportunities to learn lessons as more teachers accessed the project website over time. During Year 1, a core team of e-Coaches with content expertise in mathematics was assembled to work with instructional designers to pilot the design and implementation of the e-Modules and e-Coaching. Additionally, IT designers and systems administrators developed a website and learning management system that could be accessed by alternative certification candidates and partner sites. During Year 2, the e-Modules and e-Coaching were elaborated to provide online content in special education and principles of learning and teaching. Additionally, e-Coaches received training on the use of the video conferencing system and the KNOTtT website capabilities. In Year 3, the e-Modules and e-Coaching design teams added training resources in physics, chemistry, biology, Earth and space science, and middle school mathematics.

Furthermore, the e-Coaching sessions were expanded, with as many as three sessions in different areas offered per week. During this time, project leaders and partners paid close attention to identifying and addressing barriers to use of the online sessions. In Year 4, bilingual and Spanish e-Modules and e-Coaching were added, as were resources for pedagogical training and English/language arts. Throughout the staged approach, designs of e-Modules and e-Coaching were informed by content standards, content covered on teacher certification exams, e-Coaches' experiences as teachers and trainers, as well as conversations held between the design team and leaders at local program sites.

Balance between Standardization and Customization: The Project KNOTtT blended learning environment balanced the delivery of content that could be standardized across settings, as well as opportunities to customize learning unique to needs at each partner site. Although the structure of alternative teacher certification varied greatly across the states of Kansas, Nevada, Ohio and Texas, in three of the states, teachers were required to pass the Praxis exams for certification. And, in the state of Texas, teachers were expected to pass the TExES exams. Thus, the e-Module design team was able to standardize the content and delivery of the modules to align with the two exams. Once granted access to the website, teachers from nearly any U.S. state could access KNOTtT to review content-specific resources to prepare for certification exams.

Due to differences across state requirements and program policies, it was important that each program be allowed to customize teachers' blended learning experiences. One way of facilitating this was through face-to-face teacher preparation experiences developed by local alternative certification programs. Additionally, members of the KNOTtT core team worked with partner sites to design specific face-to-face offerings to complement alterative program courses. Customization was also supported through the use of e-Coaching. Each e-Coaching session was planned through input provided by alternative certification program staff. Several times a year, Project KNOTtT development team members met with program directors and coordinators to discuss how KNOTtT resources could further support programs and beginning teachers. The KNOTtT project manager also convened a monthly meeting with e-Coaches and alternative certification program coordinators in order to obtain information about practice challenges teachers faced so that each e-Coaching session could be tailored to address relevant teaching challenges.

Project KNOTtT e-Coaching was not designed to enable coaches to use videoconferencing or video recordings to observe participating teachers as they worked in their classrooms. Thus, coaches relied heavily on input from alternative certification program coordinators and participating teachers, their own knowledge of content covered on the certification exams, as well as their own prior experiences as teachers to determine how best to support teacher learning. E-Coaches continually asked teachers to provide information about areas in which they struggled and where they felt they could use extra support. Coaches then built on the feedback to prepare for upcoming e-Coaching sessions.

Teachers' experiences with Project KNOTtT blended learning were further customized by local alternative certification program policies and strategies for providing space and time for teachers to make use of the online components. For example, some program sites chose to weave KNOTtT as an integral part of their program by scheduling group sessions for teachers to sit together in a meeting room to attend e-Coaching. Other strategies program sites used for integration included allowing e-Coaching participation to count toward teachers' additional professional development hours, requiring teachers who had not yet completed their certification exam to attend e-Coaching sessions, increasing awareness about KNOTtT among teachers not required to attend sessions, and withholding tuition reimbursements until teachers successfully passed certification exams. One alternative certification program also assigned candidates in their program homework that required them to log in and make use of the online resources provided by Project KNOTtT.

Evaluation and Continuous Improvement: The fourth and final strategy that led to the successful use of blended learning for alternative teacher certification was evaluation and continuous improvement conducted throughout the life of the project. Evaluation efforts were formal and informal. Formal evaluation efforts consisted of examining the extent to which teachers utilized the online offerings and how they were integrated into teachers' face-to-face learning experiences. Evaluation also investigated teachers' impressions of the value of KNOTtT participation and examined teachers' sense of self-efficacy as an outcome measure. Research findings stressed the importance of programs working to ensure that teachers make use of online learning resources that can complement and extend face-to-face instruction to support their learning.

Informal evaluation also occurred over the life of the project through frequent dialogue between members of the KNOTtT core team and partner sites. During monthly e-Coaching meetings, such conversations led to incremental improvements in e-Coaching delivery. During annual planning meetings, ideas were shared on how subsequent blended learning efforts could be improved through design and implementation changes. The informal evaluation efforts led to the realization by members of the KNOTtT core team that because e-learning lacks non-verbal communication cues, the online environment calls for skills such as moving at a slower pace, monitoring wait time for responses, and succinctly presenting information. The core project team also found that conducting face-to-face sessions with each partner site was critical in establishing relationships and designing resources to meet the needs of various program partners. One of the positive aspects of planning meetings and providing teacher resources online was the increased ability to reach and manage a large group of 100 or more individuals. Through the use of video conferencing polling features, meeting facilitators and e-Coaches could quickly see whether the majority of participants grasped a concept. Additionally, as described in a previous section, program partners drew on insights gathered through informal evaluation to consider how to make more intentional efforts to integrate the KNOTtT face-to-face and online teacher training resources into local programs.

As a result of evaluation efforts, project partners identified several untapped opportunities for further blending online and face-to-face teacher preparation activities. Suggestions included placing a greater emphasis on using e-Coaching for pedagogy, which may encourage teachers to continue using the service after passing certification exams. In addition, partners recommended that e-Coaching sessions focus on helping teachers build collegial relationships within and across school buildings. Partners also suggested closer coordination with candidates' assigned mentor teachers and involving principals. A final suggestion was to establish consistent branding between local districts and Project KNOTtT in an effort to change teachers' impression that Project KNOTtT is an extra requirement, as opposed to a resource for their continued professional growth.

FUTURE RESEARCH DIRECTIONS

The research studies summarized in this chapter established a link between the amount of teachers' participation in the e-learning component of blended learning and teacher self-efficacy. Teachers who began the school year with lower-levels of self-efficacy were more likely to use the online components. Additionally, this same group of teachers reported a gain in self-efficacy by the end of their first year of teaching. Future research can examine whether blended learning participation can support gains in self-efficacy for all novice teachers, or whether it is only effective for those who begin the school year with lower levels of self-efficacy.

Although there is a growing body of research that documents the extent to which blended learning can effectively be used to support teaching and learning in a variety of contexts, given the ever-expanding possibilities for integrating technology, more research is needed that documents decision making associated with blended learning variations. For example, how are decisions made about how to balance e-learning or face-to-face aspects of blended learning in education?

While much research may focus on the interaction between student learners and blended learning components, more research is beginning to focus on implementation issues and the institutional support necessary for supporting blended learning. This chapter, however, shared details on an effort to use blended learning across a network of partners to support alternative teacher certification and induction. Future research can examine how blended learning is being used to support the learning of school leaders.

CONCLUSION

This chapter summarized some of the ways e-learning can be used to complement and extend teacher education. Through relaying an example of blended learning in alternative teacher education, authors explained how leveraging insights from Project KNOTtT's partners supported design and implementation. Partners provided insights into the needs of teachers as learners, as well as the needs of teacher preparation programs. Together, members of the core project team and partners engaged in evaluation and continuous improvement to refine blended learning and to consider ways to further support teacher learning. As technologies continue to evolve, along with goals and structures for teaching and learning, partnerships can be valuable resources for program improvement. Effective use of blended learning required not only changes to the computer technologies employed, but also changes in partner sites' structures and processes. This work emphasizes that blended learning can present many design challenges and opportunities. Thus, the mere presence of blended learning is not a panacea for education (Njenga & Fourie, 2010). Instead, programs that intend to benefit from blended learning should provide organizational support to learners to ensure participation and lead to positive outcomes (Park & Choi, 2009; Southern Regional Education Board, 2006).

KEY TERMS AND DEFINITIONS

Alternative Teacher Certification: Nontraditional, state-approved route to teacher certification that began in the late 1980s. Providers of such programs may include school districts, education service agencies, universities, four-year colleges, two-year colleges, for-profit and nonprofit organizations, or partnerships of these entities.

Blended Learning: Educational experiences that combine elements of traditional face-to-face instruction with online instruction. In such conditions, e-learning may be used as a supplement to traditional face-to-face instruction, e-learning may replace face-to-face instruction, or learners may be offered a range of online and traditional experiences and instructional resources from which they can select a desired learning path.

Coaching: A common strategy used in corporate settings to help individuals identify and address personal development and professional learning needs. Coaching is similar to mentoring in that an individual seeks assistance from an experienced advisor who can assist with improving professional practice. Mentors are typically senior organizational insiders in job positions similar to mentees, whereas coaches are carefully-selected organizational outsiders who can help an individual meet performance goals while minimizing concerns about privacy and organizational politics.

E-Coaching: Coaching that is conducted using telecommunication technologies and devices such as telephones, chat rooms, instant messaging, and Bluetooth earpieces. Benefits include coach-learner synchronous interaction, the ability for one coach to support multiple individuals while also addressing practical constraints related to location, scheduling, and costs. E-coaching sessions can also be recorded and archived for subsequent viewing.

E-Modules: Units that use a combination of text, graphics, audio, and video to deliver programmed instruction. The content is relayed to the learner in a standardized fashion and may include the use of assessments to check for understanding.

Instructional Design: A systemic process for developing learning experiences intended to address deficiencies in knowledge and skills.

Needs Assessment: A process to identify gaps in learning and to determine whether instructional design can help address learning gaps.

Professional Development: Training to improve employees' practice and job performance. The training model is time efficient, yet often decontextualized from everyday practice and occurs in discrete and finite episodes.

Professional Learning: Ongoing efforts to provide professionals authentic learning experiences that are informed by professionals' own assessments of situations in which they feel they learn best. Learning experiences are situated within a community and are likely to result in practice changes.

Chapter 4
Blended and Online Learning in Virtual K-12 Schools

Alex Kumi-Yeboah
Dalton State College, USA

ABSTRACT

Since 2000, there has been an increasing rate of online learning directed toward K-12 schools in the United States. The need for online courses has become evident as schools are searching for ways to meet student's learning needs. Online and blended courses provide options for schools with limited curricular offerings, scheduling conflicts, or find it difficult to provide highly qualified teachers. In the 2010/2011 school year, it was estimated that approximately 1.5 million students in K-12 schools across the United States were enrolled in an online course (Wicks, 2010). However, a literature search indicates that not much is known about K-12 blended and online learning instruction in virtual K-12 schools. Various issues such as types of instructional delivery, optional management skills, current trend of blended learning, the academic impact on K-12 education are critical areas for teachers and administrators to consider (iNACOL, 2011). This chapter seeks to demonstrate the growing trend of blended and online learning in the United States, analyze instructional implications of blended and online learning to students, discuss major obstacles to blended and online learning in K-12 schools, address possible solutions, and provide recommendations for further studies.

INTRODUCTION

Blended learning is a type of online learning that includes the use of learning tools such as virtual teaching, self-paced Web-based courses, electronic performance support systems, and knowledge management systems (Singh, 2003). Virtual online learning in K-12 school(s) is a form of distance learning, where teachers and students are separated by geographical distance and the class is conducted using different electronic communication methods such as video conferencing, online chat, synchronous conferencing, web conferencing, blogs, emails, and social networks (Wicks, 2010). According to Watson (2010), the millennial generation students in K-12 schools today are children of a digital age and are typically far more comfortable with technology than their parents and teachers. K-12 online learning is another branch of instructional delivery that is growing rapidly and

Source: State high school population, http://nces.ed.gov/programs/statesprofile/

evolving in many different directions. It is merging with face-to-face instruction to augment time as well meet the needs of all students (Watson, 2010). The International Association for K-12 Online Learning (iNACOL) 2012 annual report indicates that students enrolled in K-12 virtual online schools have increased significantly and in addition 39 states offers state-led blended and online education programs at the K-12 level (see Table 1 and Table 2) (Watson, Murin, Vashaw, Gemin, & Rapp, 2010). For example, Florida has the largest number of virtual students with over 220,000 course enrollments in 2009/2010 academic year (Watson et al., 2010). The current trend of social media and increased use of technology among the youth makes online learning an option for teachers to consider using to support the teaching learning process (iNACOL, 2011). It is estimated that 44 states offer blended and online education opportunities for K-12 students through either state supplemental program, full-time online programs or both (Watson, Gemin, & Ryan, 2008).

According to iNACOL (2012) annual report, the main reasons why many school districts provide fully online learning or blended (hybrid) learning to their students is to provide courses that are not available at their schools as well as provide opportunities for students to recover course credits from classes missed or failed. In most urban schools, blended learning and online learning become an alternative option to increase student graduation rate and credit recovery for students in the adult education and drop-out prevention programs (Watson, 2010). Watson (2011) reports that the increasing growth of K-12 online schools are attributed to: (a) provide opportunities for students to take credit recovery classes especially for urban

Table 2. Sample of States with State Virtual Schools that have Remained or Become Small in 2012

State Virtual School	Course Enrollments	Annual Growth	Ratio to State Population
Connecticut Virtual Learning Center	2,049	-7%	1.2
Illinois Virtual School	2,795	-7%	.4
Texas Virtual School Network	12,419	-27%	.9
Kentucky Virtual Schools	1,700	-1%	.9

Source: State high school population, http://nces.ed.gov/programs/statesprofile/

schools; and (b) enroll in advanced placement courses in English, mathematics, social studies, and science (Watson, 2011). Again, K-12 students are motivated by online learning and have the maturity and self-discipline to work independently and have the propensity to succeed on online courses (Hilz et al., 2004). It is important for teachers in K-12 schools, educators, researchers, and policy makers to get information on blended and online learning in K-1 schools. This chapter seeks to demonstrate background information on blended and online learning in the United States; analyze and synthesize instructional implications of blended and online learning to students; allow discussions on major obstacles to blended and online learning in K-12 schools; address possible solutions, and recommendations for further studies.

BACKGROUND

K-12 Blended Learning Models

According to Smith, Clark and Blomeyer (2005), it is estimated that in 2005, one in 100 students in the United States K-12 public school took at least one course online or combined (blended or fully online). Blended learning mixes various event-based activities, including face-to-face instruction, live e-learning, and self-paced learning (Singh, 2003). Blended learning is sandwiched between fully face-to-face and online instruction (Graham, Allen, & Ure, 2005; Watson et al, 2010). In most cases, blended learning is used interchangeably with hybrid learning. Blended learning can be delivered in a variety of ways such as structured and unstructured learning. A structured blended learning program occurs when the content is organized. It encourages students to be actively engaged and allows the instructor to track student use of the program, manage access to the next stage on the basis of completion or assessment, and follow up with another form of communication to students who are not completing work (Hoyle, 2003). In unstructured blended learning, students have opportunity to interact and collaborate with other students with less monitoring. They are able to collaborate on group projects or discussions that promote student-centered learning (Hoyle, 2003). Further, blended learning utilizes both offline and online settings. The offline setting involves instruction delivery in a traditional face-to-face classroom while instruction in the online setting consists of the use of the Internet. Blended learning utilizes the atmosphere of both offline and online setting. Offline learning happens in a more traditional classroom setting. Offline learning offerings are managed through an online learning system. An example of this type of blending learning includes a learning program that provides study materials and research resources over the Web, while providing instructor-led, classroom training sessions as the main medium of instruction, this is also known as asynchronous and synchronous learning (Singh, 2003).

Synchronous and asynchronous learning are both types of Internet communication tools that can be utilized in blended and online learning to fulfill the technology requirement. Synchronous learning or events happen at the same time for everyone, but can be online to include the use of online meetings, virtual classrooms, Web seminars or conferencing or IM chats and broadcasts coaching, and instant messaging conference calls or offline (students listening to a lecture in a classroom) while asynchronous learning means students can learn the same content (pre-recorded lecture, notes posted online, Web-based simulation) at different times. It can also be offline, i.e., students visiting the same museum exhibit at different times. It can occur as an instructor-led classrooms and lectures, hands-on activities in the classroom, laboratories, workshops, and field trips (Singh, 2003). This means that an asynchronous learning environment provides students with teaching materials and tools for registration, instruction, and discussions outside of the classroom scenario and incorporates the ability to maintain communication with tutors and other students outside of rigid educational timetables. It makes an extensive use of software and the Internet, using technology packages like blackboard, e-mail, or chat rooms. Students have access to post, read and respond to subject instruction, queries and messages all within the same shared space.

According to Bremer (1998), asynchronous discussion has the potential of helping K-12 students who do not participate and collaborate with their peers within the traditional classroom. Students have the ability to work at their own pace and control the pace of instructional information in the classroom (Bremer, 1998). According to Stockley (2005), blended learning is a type of online learning that describes learning or training events or activities in various forms. The main purpose of blended learning model is to pair the best features of face-to-face teaching with the best options of online learning to promote active and independent learning. The hybrid model has components of instructional technologies that combine lecture or laboratory content into new online learning activities, such as case studies, tutorials, self-testing exercises, simulations, and online group collaborations (NJIT, 2005). Hybrid courses involve a great amount of technology. They also greatly increase the independence of the student by allowing him/her to work at his/her own pace outside of the typical classroom. The success of blended learning in K-12 schools can be attributed to the interactive capabilities of the Internet use and face-to-face teaching (Garrison & Cleveland-Innes, 2003; Swan, 2001).

Blended and Online Learning in K-12 Schools

According to Picciano and Seaman (2007), about three-fourths of U.S. students take either fully online or blended (combination of on-and off-line) courses, with majority of students enrolled at the high school level. Online and virtual K-12 schools have become popular as a result of the flexibility to its content and instruction. This is due to the following (a) assembling and disseminating instructional content more efficiently; b) increasing the availability of learning experiences for those who cannot or choose not to attend traditional schools; and c) increasing student-instructor ratios while achieving learning outcomes equal to those of traditional classroom instruction (Riel & Polin, 2004; Schwen & Hara, 2004).

Virtual online education at the K-12 level is offered as full-time comprehensive schools, combination of traditional face-to-face and online programs, charter and private schools as well in e-learning programs within the school and hybrid courses. Virtual online learning is administered at the state, school district, and private sector levels (Watson, 2011). K-12 online programs are funded in different forms such as state's government, grants, scholarships, student tuition, and school-based courses subscribed by students. Presently 40 states have fully implemented virtual schools or state-led initiatives with 30 states including Washington D.C. offering full-time online schools (iNACOL Report, 2012). Current trends in social media and access to technology provides opportunities in online learning for K-12 students in about 48 states and Washington, D.C. (Watson et. al, 2010). The International Association for K-12 Online Learning (iNACOL) reported that about 1.5 million students took one or more online courses in 2010 (Wicks, 2010). For example, states of Alabama, Florida, and Michigan have all made online learning experience part of their graduation requirements (Watson et al., 2010). Furthermore, Singh (2001) explains that blended learning is making an increasing way into elementary, middle, junior high, and high schools around the country resulting from the flexibility of time for students and teachers. Again the present shortfall of budget and increasing student population has called for more online and blended learning to satisfy student needs. Belanger (2005) contends that students who are involved in online learning during the middle school years are more likely to keep their academic grades higher than those who are not exposed to online learning.

Oakes and Casewit (2003) further explain that the best practices in blended learning includes:

- Create a structured core curriculum of learning activities that are taught using a variety of instructional methods;
- Support an environment in which students can learn smaller parts and work their way up to more complex ideas;
- Create a classroom in which students can learn informally;
- Provide technological support and for students; and
- Provide an easy to use environment.

According to Oakes and Casewit (2003), the above best practices provide an important management and operational academic support for students who will opt for blended learning. Cavanaugh, Gillan, Kromrey, Hess, and Blomeyer (2005) reported that there were no statistically significant differences in achievement between online and conventional courses. They reviewed the results of 14 studies published between 1989 and 2004 that compared online courses with face-to-face courses with critical look at the internal experimental validity. Tallent-Runnels et al. (2006) reported that there were no differences between learning outcomes of the traditional and online instruction of K-12 students after a review of the achievement in online courses across variables of age and subjects. A meta-analysis study conducted by the U.S. Department of Education (2008) examined 51 independent effect size measures that compared studies on K-12 online and traditional face-to-face education between 1996 and 2008. The study found that students in online instruction performed academically better than those in the traditional face-to-face instruction. Additionally, there are differences in online programs with regards to grade levels, type of students, and programs. However, most online programs showed common characteristics using qualified teachers, digital course content, and learning management software to deliver education to meet a significant proportion of student needs (Watson, 2007).

Watson (2007) conducted a study about K-12 online learning that reviewed an extensive literature about policies on online learning. Result shows that there was a significant relationship between types of students served, grade level, and program of study. Rockman et al. (2007) conducted a study that evaluated the effectiveness of Spanish classes offered to middle schools (seventh and eighth grades) in West Virginia Virtual School. The study was comprised of 463 students in 21 schools. The purpose of the study was to compare student's class performance in combined face-to-face instruction and blended learning and virtual schools with regard to school size and average language arts achievement. Result indicates that there was a significant difference between students in the face-to-face instruction and those in the virtual program. Students in the blended learning program performed better than those in the face-to-face instruction program. O'Dwyer, Carey, and Kleiman (2007) investigated the learning outcomes of students in an online Algebra 1 class and students in the traditional instruction with regard to mathematics ability, environment, and size using quasi-experimental design. Researchers developed multiple choice tests questions for both students in the combined face-to-face and virtual schools. Result shows that online students outperformed better than those in the traditional classrooms.

Englert et al. (2007) investigated the effectiveness of a Web-based writing support program. Participants included 35 elementary school students in a special education class across five urban schools. Students were divided into treatment and control groups. Students in the treatment group used Web-based program in writing performance. Control group students used writing tools in a traditional instruction. Students in the Web-based support program performed better with an effect size +0.74 than those in the traditional face-to-face instruction. Wang et al. (2006) investigated middle school students in a virtual biology course using formative online self-assessment and traditional tests. The study used a quasi-experimental design. Students in the virtual biology course performed higher than those in the traditional tests.

There are many instructional online activities that can be used by K-12 students engaged in blended learning. The following websites will be useful for both teachers and students at the K-12 level.

http://pbskids.org/zoom/games/kitchenchemistry *(Zoom Kitchen Chemistry)*: This website enable students to learn and conduct real-life practical experiment at home using kitchen tools as apparatus. Students have the opportunity to explore virtual kitchen and can perform online experiments to solve a puzzle as well as get a reward. The site provides opportunities for students to study science (chemistry) outside the classroom using technology.

http://starchild.gsfc.nasa.gov *(StarChild):* This site provides information about space and the solar system for K-12 students. It is anexcellent web resource student to study introductory astronomy. The site is divided into two levels and other sections. The first level consists of activities on solar system, basic information on the universe, and glossary of science terms. Level two consists of movies and videos on the solar system, the universe and vocabularies of key terms. The site has a section termed "in the classroom" that consists of the teacher center which provides information and activities found in StarChild that can be used to engage, excite, and educate students in the classroom. Another advantage of this site is that it can be used in other languages to help English as a Second Language Learners (ESOL) to learn science online. Finally, the sites provide information about other websites on space and the solar system that could help kids to study and learn science online. Some of the websites within this site are:

1. The Nine Planets http://nineplanets.org/
2. The Space Place http://spaceplace.jpl.nasa.gov
3. Astronomy for Kids http://www.kidsastronomy.com/index.htm and
4. Amazing Space http://oposite.stsci.edu/pubinfo/education/amazing-space/

http://nlvm.usu.edu/en/nav/vlibrary.html *(National Library of Virtual Manipulatives)*: This site provides information to about how to use manipulatives to teach mathematics at the K-12 level. As a virtual library, students can use java applets to do hands-on experience to solve math problems.

http://www.readingmatrix.com/directory/pages *(The Reading Matrix)*: This site has resources in reading, comprehension for beginning and intermediate readers, reading matrix blogs, and proofreading. Students have an opportunity to practice comprehension and vocabulary questions as well as use the interactive activity games at home.

*National Geographic for Kids (*http://www.nationalgeographic.com/kids*)*: This site contains games, cartoons, current events news, photos, videos, countries, and information of various animals and communities around the world. This site will be a great resource for social studies at the K-12 level. The site provides opportunities for students to research about the history, geography, and environmental issues that affect their communities, states, nation and the world.

In sum, online and blended learning may be considered one of the most important instructional models in the current technological dispensation at the K-12 education. The literature has provided information about the models/curriculum that instructors could use to teach in the blended and online learning environments. Students in K-12 schools are at pace with current technology in the classroom and the content of delivery. Literature has shown that students performed significantly better in online instruction than those in the traditional face-to-face instruction. The literature addresses the situation to determine which of the instructional methods will best suit students and teachers in the teaching learning process in K-12 schools.

BENEFITS OF K-12 BLENDED LEARNING TO STUDENTS

Blended learning allows teachers to focus on the best teaching strategies and innovative ideas they have to implement for students' success in the classroom. Teachers have the ideal opportunity to monitor students' academic progress as well as vary their instructional strategies to suit the needs of all students. Blended learning provides students the best learning environment in the teaching learning process. Students have an easy access to contact teachers for assistance after class (face-to-face instruction) in the online section. This is an advantage for students to understand concepts they learn. The online version of blended learning affords students the opportunity to demonstrate their learning abilities through the use of computer-based resources. For example, discussion forums are great for students who feel shy to participate in the traditional face-to-face instruction. Further, blended learning provides an opportunity for students who do not participate in face-to-face instruction to gain complete confidence in online discussions (Cavanaugh, 2008; Christensen & Horn, 2008; Christensen, Johnson, & Horn, 2008; Kearsley & Shneiderman, 1998; Moe & Chubb, 2009; Wilson, 2010; Wise & Rothman, 2010). The online course component of blended learning has the potential to improve students' learning outcomes as compared to the traditional teaching methods such as lecturing and note-taking. Students have the flexibility of participating in class either online or face-to-face instruction that may suit their learning style (Twigg, 2003). Blended learning helps students to engage in active learning which leads them to develop deeper learning. This is achieved through the use of discussion forum, use of blogs and chats, video conferencing, online interactive activities/simulation, and online assessment with feedback. Online learning allows students to experience simulations and visualizations that challenge them to extend abstract information to concrete concepts (Eastman & Swift, 2002).

Blended learning programs facilitate situated understandings, multiple perspectives and transfer through immersive experiences and activities (Dede, 2009; Gee, 2010). For Instance, In Vermont, Middlebury College and K-12 Inc developed an interactive language programs to provide experience for K-12 students through an immersive technologies such as 3D games and social networking. The majority of online learning programs at the K-12 levels support the learning needs of students such as English as second language learners, students with disabilities and gifted students. These students have the opportunity to participate in the online instruction (discussion forum or online chat) with less difficulty. They can use chat room, IM or e-mail to work together to complete a project. Additionally, the use of modules in online learning environment and free access to learning resources allow students to progress at different levels and promotes differentiated learning that is, teachers are able to design instruction based on student needs. As a result of the diverse background of students in the classrooms around United States students stand to benefit tremendously from the dual component of blended learning (Archambault et al., 2010; Christensen & Horn, 2008; Waldeck, 2007; Watson & Gemin, 2008).

Online learning offers K-12 students feedback and communication about their performance. Communication tools such as discussion boards and chat rooms in online learning can be effective in inter-team collaboration as well as in teacher-student communication. The use of online assessment at the K-12 level allows efficient data collection about individual and group performance that would be difficult to collect in the traditional classroom. For instance, online quizzes and tests give students and teachers instant feedback about their scores. Teachers do not have to go through the long process of calculating grades or quizzes. Assessment in blended learning works in such a way that parents, teachers and students all have access to grade promote transparency (Dennen, 2005; Rice, Dawley, Gazel, & Florez, 2008). Online assessments come with accessibility and support systems that is universally designed to meet the need of students with disability and English language learners (Almond et al., 2010; Kopriva, 2009; Rose & Meyer, 2000; Russel, Hoffmann, & Higgins, 2009).

Blended learning provides ample time for teachers to effectively use their instruction time for more students at a particular place. It has the potential for increasing the number of students served by the teacher. Because teachers can serve large number of students at a particular time to save space and time. Students have access to online resources such as dictionaries, encyclopedia, and research in the course of the teaching-learning process. For instance, expelled students or students on suspension who are required not to attend the traditional classroom as a consequence but still can have access to material to prevent falling behind academically (Moe & Chubb, 2009; Repetto, Cavanaugh, Wayer, & Liu, 2010). Again, students who have opted to be home-schooled with instruction in subjects their parents feel unable to teach learn those subjects and assist with the aid of resources accessible to them online. Students who have been hospitalized or handicapped and cannot attend or travel to the traditional face-to-face classroom will have access to resources, work through the class content while receiving treatment. The use of blogging in the blended and online learning has a high impact on instructional implications in the high school. It helps students exchange ideas about literary activities such as think-aloud postings, literature circle group responses, and round table discussions. Example is where students at Hunderdon Central Regional High School in Flemington, New Jersey used blogging to discuss "The Secret Life of Bees" by Sue Mon Kidd in an American Literature class (Bull & Kajder, 2003; Toto, 2004). The use of blogging as an online instructional tool helps students in K-12 schools improve on their writing in terms of planning, drafting, revising, editing, proofreading, and presenting as well as grammar skills. It promotes collaboration and offers an opportunity for students to become deep learners and acquire critical thinking skills as well as to reflect on what they learn as compared to learning in the traditional classroom. Students have the means to deliberate on concepts they learn in class and apply it to real world situations (Toto, 2004).

Through blended learning, students develop skills of analyzing, reflecting and critical thinking through active response to Internet resources. This allows students in K-12 schools to define their positions in the context of other people's opinions on a particular issue. It is important for teachers to recognize the role of technology in the curriculum taking into consideration the current wave of growth and awareness of technology use by students in the classroom. For instance, students who participate in blended learning gain advanced technological competencies such as online quiz, online chats, forum discussions, and efficient use of multimedia and hypertext tools (Oblender, 2002; Oravec, 2002).

Instructional Implications on Student Learning

With the use of blended learning, at the K-12 level, teachers will be able to alter the learning environment for students to work collaboratively in learning communities online. For example, Teachers may add significant curriculum content resources that could be difficult to comprehend outside of the Internet or online. For example, in a study conducted by DeLacey and Leonard (2002), indicated that blended learning promotes student interaction and satisfaction in courses that incorporated blended learning. Furthermore, the use of blended learning allows pacing and attendance in the classroom. In blended learning instruction students have the advantage to choose their own time to study. Again, if a student is absent to class, he/she may have an opportunity to view and access to missed materials at the same time that the rest of the class does, even though the student cannot be physically in the classroom. This provides an opportunity for the student to stay on track and not fall behind. This is an advantage to students with disabilities or students who may not able to attend class as a result of sickness or injuries. Another impact of blended and online learning on students at the K-12 level is that teachers may have more available time to monitor progress and provide support to students who may lag behind. Blended learning courses provide physical resources that are not available in courses that are presented completely online, including language, technology and science laboratories (Oblender, 2002).

Blended and online learning has an element of self-paced modules that allows students to review content materials at any time to be able to understand a concept or to work ahead for those students who learn at a faster pace (Alvarez, 2005). The self-pacing classroom nature of blended learning allows a higher completion rate for students than those in the fully online situations because it gives students varying options to choose from such as online discussion forum, online chats, use of video, and other hypermedia tools (Flavin, 2001). Blended learning allows teachers through the use of Internet and other technologies in the classroom to structure their instruction to meet the learning needs of all students and teaching styles of teachers (Alvarez, 2005). Alvarez (2005) stated that

the online environment is not the ideal setting for all types of learning. Classrooms are not perfect either… That's why so many teachers and corporate trainers are concentrating their efforts on integrating internet-based technologies and classrooms to create blended learning environments. It just makes good sense.

Combining different delivery modes has the potential to balance out and optimize the learning program development and deployment costs and time. A fully online content could be expensive to produce (requiring multiple resources and skills), however, combining online collaborative and mentoring sessions with self-paced materials, such as generic off-the-shelf WBT, documents, case studies, recorded e-learning events, text assignments, and PowerPoint presentations (requiring quicker turn-around time and lower skill to produce) may be more effective (Singh, 2003).

Blended and online learning provides an opportunity for at-risk students to receive peer-to-peer interactions needed for collaboration to provide them a sense of responsibility. Also the presence of the instructor is more frequent, and results in more meaningful dialogue between teachers and students (Newlin & Alvin, 2002). A typical example is that of the Mannheim Township Virtual High School in Pennsylvania, where a hybrid online and traditional course model increased the graduation rate to a 99% (Oblender, 2002). Another important aspect of blended learning in K-12 schools is that teacher availability extends beyond the confines of the school day and the school building with expanded learning opportunities for all students. Students have time and availability to contact teachers through telephone, email, and other online sources for academic help at any particular time and space (Morehead & Labeau, 2004).

Finally, blended and online learning has the potential to reduce the amount of space to serve larger number of students in densely populated school districts. For example, the Albuqerque's eCADEMY provides about 80% online and 20% on-site instruction to K-12 students (Watson, 2010). Building cost of eCADEMY is reduced to about one-seventh and serves half of the student's population on-site. Another example is that of Carpe Diem Collegiate High School and Middle School in Yuma, Arizona, where labor cost was reduced into half as a result of blended learning (Watson, 2010). Only six certified full-time teacher in addition to support staff serves about 274 students. The school has only five traditional classrooms and the capital expenditure per student is reportedly less than half that of any school building in the same area (Staker, 2011).

MAJOR OBSTACLES TO K-12 BLENDED LEARNING

Blended learning at the K-12 level is not without any challenges. Considering the fact that most blended learning programs are at its initial stage, the development of a successful blended learning program comes with major challenges such as teacher training, cost of delivery, copy right issues, lack of social interaction among students, teachers, and policy issues. A major challenge to blended learning is the security concerns with regards to incorporating e-learning in the K-12 curriculum surrounding the use of the Internet. Many concerns have been raised by parents on the security of online learning by K-12 students, making them to refuse to sign off on allowing their child unrestricted use of computers while they are at school. School districts spend sizeable amount of their budget to install filters and firewalls that attempt to block unsuitable sites, but they are not always successful. As a result of the No Child Left Behind and Race to the Top mandates, most school districts are shifting their resources to teacher effectiveness and student test performance and shifting funding from expanding computer access for students to needing more computers for bookkeeping purposes.

According to Watson (2010), funding of online learning for students at the K-12 level in several states is a major issue to deal with in some school districts. Watson (2010) further explains that it is due to the fact that online schools sometimes draw students across district lines, and funding often follows the student. Thus, students leave “home” school district for the online school, resulting in a drop in funding for that school district. Another challenge to blended and online learning is having all students’ equal access to online instruction. Income gaps have created situations where some students have access to a computer, basic software, and the Internet. However, for students in poor inner-city and rural areas, access to computers and Internet is a major challenge (Watson, 2010). More so, online courses can pose challenges for students with learning or physical disabilities. It may be difficult for some students with learning or physical disabilities to access Internet use independently without any help from teachers or parents. It is evident that certain students with learning or physical disabilities may not be able use technology and communication tools involved in blended and online learning at the K-12 level to (include online discussions, blogging, chats, and simply the use of emails or telephone). Lack of qualified instructional technology staff is a major challenge to managing successful blended learning program. A typical example is that of shortage or lack of IT staff in states like Louisiana, Georgia, and Florida (Project Tomorrow, 2010). Not many instructional staff have been offered trainings on technology or how to teach online and in 2010, only 12% of new teachers reported receiving college or university training on online education (Dawley, Rice, & Hinck, 2010). Again, only four percent of students aspiring to be teachers at the K-12 level indicated in the Project Tomorrow survey that they have received training on how to teach online classes in their instructional methods courses (Project Tomorrow, 2010).

Additionally, the rising growth in online education has outpaced education policy in several states (Watson, 2010). For example, in many states such as Florida, Alabama, Georgia, Ohio, and California; online programs are guided and overseen by rules and regulations created for traditional schools. According to Watson (2010), in 2001, the National Association of State Boards of Education stated "In the absence of firm policy guidance, the nation is rushing pell-mell toward an ad hoc system of education that exacerbates existing disparities and cannot assure a high standard of education across new models of instruction."

Another challenge of blended and online learning is that of content knowledge and lack of awareness by policymakers and educators. There are situations where educators and policymakers are fully unaware of the basics information on how blended/online education programs operate, the curriculum content of online courses or programs, and how students can learn online as compared to traditional face-to-face instruction. Despite many successes of blended and online learning programs, it should be pointed out that there are concerns about the quality of online learning and issue of accountability. Few research exists about the accountability and quality of blended learning in K-12 schools, thus research in K-12 online education is minimal (Dillion & Tucker, 2011). For example, a meta-analysis and review of online learning studies by the U.S. Department of Education concluded that limited number of published studies exists on K-12 online education (USED, 2010). There is lack of knowledge that identifies the elements of pedagogy and best practices in teaching online education. For example, not much is known about the best practices of online learning at the K-12 level that will augment student academic progress (Black, Ferdig, & Dipetro, 2008).

SOLUTIONS AND RECOMMENDATIONS

According to Patrick and Powell (2009), to reduce the challenges facing K-12 online education, it is important to transform teaching and learning by redesigning traditional classroom approaches, promote quality teaching, and enhance quality of learning experiences. It could be beneficial for colleges of education to partner with local school districts and offer professional development trainings to instructional staff in K-12 schools. This will help to transform schools of education into digital-age learning world and teacher educators who are better prepared to embrace the digital age and manifest the characteristics of 21st century teachers (Resta & Carrol, 2010).

Teachers and educators in K-12 schools should be offered online education trainings in areas such as technical and pedagogical foundations, ethical issues related to online courses, skills in online management systems, and use of asynchronous and synchronous features. Online education could be incorporated into the curriculum of teacher education preparation programs for pre-service teachers. College of education in the various universities should partner and collaborate with school districts to promote the expansion of online education in K-12 schools. For example, there is a partnership between University of Central Florida and University of South Florida with Florida Virtual School (FLVS), which started in 2003 to provide virtual student teaching and internships. Several staff at the FLVS participates in introductory teacher-preparation classes by providing information about teaching online (Project Tomorrow, 2010). This could be a model for other states and college of education to initiate a partnership on instructional technology.

Additionally, more funding should be made available to K-12 online education in the various colleges of education and local school districts to help transform instructional technology in K-12 schools to meet the rapid growth of technology in the 21st century. Equal access to online education should be made available to all students regardless of their location and socio-economic status. To reduce the discrepancies of standards between states, common national competency standards could be established for digital-age teachers as a means to ease state-to-state reciprocity (Resta & Carroll, 2010). To promote quality of online education, colleges of education, teacher education preparation programs and school districts could provide alternative teacher certification programs in online endorsement that includes online instruction and performance-based certification for teachers to transfer teaching certificates without any problem (Foundation for Excellence in Education, 2010).

Administrators, educators, policy makers, and law maker in various states could be educated and informed about the basics of online education, benefits and challenges involved in establishing successful online education program to augment the fundamental understanding of K-12 online education among school administrators, teachers, policy maker, and law makers. More research could be conducted about the best practices and pedagogy in K-12 virtual schools and what instructional methods could make teachers effective in online environments. It is important that students, educators, policymakers, and the online programs collaborate to find common agenda on where they exist, and what holds in the future.

FUTURE RESEARCH DIRECTIONS

This chapter contributes to blended and online learning in virtual K-12 schools in the United States. This Chapter demonstrates that blended and online education at the K-12 level can empower students to develop skills in analytical and critical competencies through active response to Internet resources. This allows students to define their positions in the context of other people's opinions on a particular issue (Oravec, 2002).

The educational implication of this chapter is that it adds to the available literature on blended and online learning in virtual K-12 schools. It also shares information about the benefits of blended and online education at the K-12 level as well as the challenges of implementing online education in K-12 schools. For example, the chapter discusses the need for school districts, teachers, and administrators to recognize the importance of blended and online learning to students. It also highlights the trend of blended and online education in K-12 schools and the instructional pedagogy involved. The chapter provides information about various blended and online education at the K-12 level, models of instruction, benefits, challenges and future directions of research. It further provides information to teachers, pre-service teachers, and administrators on the existing situation in blended and online learning environments.

Future investigation should be conducted about the relationship between fully online education and blended learning for at-risk students' academic performance. Another study could be investigated on the best practices and pedagogy in teaching K-12 students in blended learning environments. Additional research could be investigated on effective professional development curriculum on blended learning and online learning for K-12 teachers. Furthermore, future research should investigate the perception of students, administrators, and teachers about blended learning as compared to other students and teachers in other countries. There can be more research in areas of the relationship between students' performance in fully online learning and blended learning.

KEY TERMS AND DEFINITIONS

Asynchronous: Distance learning instructional tool where students can learn the same content (pre-recorded lecture, notes posted online, web-based simulation) at different times. It could be an existing or occurring at the same time.

Blended Learning: A form of distance learning that combines different forms of instructional technology (e.g., videotape, CD-ROM, Web-based training, film) with face-to-face instructor-led instruction depending on availability and resources in the context of location.

Distance Learning: A type of learning that takes place where a significant section of the teaching is conducted by an instructor not in the classroom or in space and or time from students. Communication is through email, electronic forums, video conferencing, chat room, bulletin boards and other computer-based communication.

E-Learning: The use of computer network technology, primarily via the Internet with the purpose to deliver information, content of knowledge, skills, and instruction to learners on a one-way (asynchronous).

Instructional Technology: Instructional technology is the design, development, utilization, management, and delivery of instruction either through media, electronic, print and other technology (computers, audiovisuals and equipment) as well as the evaluation of instruction for learners.

Synchronous: An instructional distance learning tool that happens at the same time for everyone, but can be online using (Web conferencing or IM chats or offline. Not going at the same rate or exactly together with something else.

Traditional Face-to-Face Instruction: Is a form of instruction that requires teachers and students to single location (classroom) with a fixed amount of time for interaction between instructor and students at a specified time in a particular place and time (classroom).

Virtual Online: A form of distance learning, where teachers and students are separated by geographical distance and the class is conducted using different electronic communication methods such as video conferencing, online chat, synchronous conferencing, web conferencing, blogs, emails, and social networks.

Chapter 5
Factors Predisposing Academics towards the Use of Blended Strategies:
A Model

Geraldine Torrisi-Steele
Griffith University, Australia

ABSTRACT

Universities are investing considerable resources into blended learning as an institutional strategy to respond to pressures of uncertain economies, increasing globalisation, and the changing expectations of cohorts of digitally savvy students. However, the widespread adoption of effective blended teaching practices has generally not been achieved. A greater understanding of academics' blended teaching practices is needed to facilitate the uptake of effective blended practices on a larger scale. By exploring how various factors influence academics' use of technology with face-to-face teaching, the study makes a contribution to the understanding of academics' blended practices. The study described in this paper uses a mixed method, two phase methodology to develop a predictive model of blended strategy use. A major finding of the study is gender differences in factors predisposing academics towards blended strategy. Factors predisposing academics towards the use of blended in strategies in current practice were found to be: perceived usefulness (but only for male academics), higher education teaching experience, and self-efficacy (but only for females). Significant factors influencing academics' intentions for future blended practice were found to be: perceived usefulness, current use of blended strategies and, for female academics, perceived feasibility.

INTRODUCTION

Significant strategic investment is being made by universities into the use of technology for teaching (Bonk & Graham, 2006; Bonk, Kim, & Zeng, 2006; Graham & Robison, 2007). The focus on technology in teaching is largely an institutional response to a number of factors including pressures of globalization, increased focus on quality teaching and learning, and the needs and expectations

DOI: 10.4018/978-1-4666-8246-7.ch005

of cohorts of digitally savvy students. As a result of the strategic focus on technology for teaching, the majority of academics are using technology to some degree in their teaching. However, only a minority of academics are successfully combining technology with their face-to-face teaching to provide effective, high quality learning experiences through the use of blended approaches (Collis & Van Der Wende, 2002; Graham & Robison, 2007; Driscoll, 2002; Hoffman, 2006). The majority of academics are using technology with face-to-face teaching mainly for reasons of efficiency and flexibility. Whilst efficiency and flexibility are important considerations for coping with larger, more diverse student populations, the success of blended approaches as an institutional strategy rest largely on the widespread adoption of effective blended teaching practices - which has generally failed to occur (Graham & Robison, 2007).

One reason why effective blended teaching practices are not being widely adopted is that using technology together with face-to-face teaching is a complex undertaking. Using technology in teaching requires significant course redesign, usually involving the creation of new learning activities and reconsideration of assessment methods (Garrison & Kanuka, 2004). Although most academics are well-versed in teaching in traditional settings but they may need to acquire the knowledge and skills to fully exploit the potential of technology to provide effective learning experience. Against this context, the need to provide appropriate professional support to facilitate the use of effective blended teaching approaches is self-evident. The research described in this paper is not concerned directly with the provision of professional support. Rather, the research is concerned with seeking base knowledge that will contribute towards the development of more effective professional support.

The premise underlying the research is that professional support needs to effect a connection to existing practice to facilitate the critical analysis of existing beliefs and assumptions that academics need to undertake if they are to transform their practice. Hence, understanding the factors shaping academics' blended learning practices is fundamental to the provision of the professional support needed to facilitate the uptake of effective blended practices on a larger scale. Unfortunately, existing blended learning literature provides meager insight into academics' blended practices (Torrisi-Steele & Drew, 2013). The research described in this paper thus stems from the need to better understand academics' blended teaching practices.

In an effort to contribute to a greater understanding of academics' blended teaching practices, the present study aims to identify factors which predispose academics to use technology to create blended strategies by developing a model predicting academics' *current* and *intended future use* of blended strategies. A review of relevant literature together with a conceptual framework enabled the proposal of research model. A mixed methods, two-phase methodology was then used to develop the model. In the first phase, a survey instrument was designed and distributed to academic staff within Griffith University. Using the data collected from the survey, regression was used to refine the theoretical model. In the second phase of the study, survey respondents were purposefully selected, on the basis of quantitative results, to participate in interviews. The qualitative data from the interviews was used to support and enrich understanding of the quantitative findings.

But First – What is meant by 'Blended Learning'?

Before describing the study, it is important to consider what meant by the term 'blended learning' in this instance of research. A simple, broad understanding of the term 'blended learning' is that it refers the use of technology together with face-to-face teaching. However, to clearly distinguish between uses of technology with face-to-face teaching that are considered blended learning and those which are not a more precise definition of the term is required. Unfortunately, there is a lack of consensus about the meaning of the term 'blended learning' and, as Driscoll (2002, p. 1) observes, the term 'blended learning' "means different things to different people". In order to gain further insight into the term, and in search of a specific definition for the present study, the author examined the use of the term 'blended learning' in both literature and across twenty Australian universities. The investigation revealed a great variety of definitions (Author, 2011). It was found that the existing definitions of blended learning were unsatisfactory for two main reasons. Firstly, many definitions were considered too broad, conceptualizing blended learning as a combination of various learning styles, and/or delivery modes or even as a mix of methods of philosophies with or without the use of technology (e.g., Singh & Reed, (2001); Verkroost, Meijerink, Linsten, & Veen, (2008)) - such broad definitions enable almost any teaching practice to be considered 'blended'. Secondly, many definitions were techno-centric and gave little pedagogical guidance (e.g., Falconer & LittleJohn (2007); Koohang (2009)). As Oliver and Trigwell (2005) suggest, definitions of blended learning need to focus on the learning experience rather than the technology to clarify that the aim of blended learning is to provide a quality learning experience and does not use technology for its own sake. A few of the definitions encountered encapsulated some pedagogical principles For example, Garrison and Kanuka (2004, pp. 96-97) view blended learning as "the thoughtful integration of classroom face-to-face learning experiences with online learning such that we are not just adding on to the existing dominant approach or method".

On the basis of the investigation described briefly above, a new 'learning-centric' definition of blended learning was formulated (Torrisi-Steele, 2011). For the purpose of the research described in this paper, that definition will be used; thus, 'blended learning' refers here to learning achieved through enriched, student-centered, experiences made possible by the harmonious integration of various strategies combining face-to-face interaction with information and communication technology.

RESEARCH MODEL

The study aims to find a model of factors that influence the likelihood of academics using blended strategies currently and in the future. Accordingly, the proposed research model (Figure 1) is comprised of factors that are potentially significant in predicting the use of blended strategies by academics. The research model is founded on the core constructs of the technology acceptance framework (developed by Davis 1989) perceived ease of use, perceived usefulness, behavioral intent (*intended future use* of blended strategies) and actual system use (*current use* of blended strategies). The predictor constructs are normative influences, perceived ease of use, perceived usefulness, perceived feasibility, prior teaching experience, self-efficacy and teaching approach. Notice that gender is considered a moderating variable rather than predictor construct. Venkatesh, Morris, Davis and Davis (2003) include gender as a moderating variable in the Unified theory of acceptance and use of technology (an evolution of the original technology acceptance model). Furthermore, existing studies on academics' use of technology have reported gender differences in areas such as perceptions of success in the use of technology (Lumpe & Chambers, 2001), and in the extent of technology integration, skill and perception of skill (Briesser, 2006; Markauskaite, 2006; Volman &Van Eck, 2001).

The technology acceptance model forms the bedrock of the research model shown in Figure 1 but there are other elements to the conceptual framework for the research. These elements are: constructivist philosophy (Jonassen, 1994), diffusion of innovation (Rogers, 1995), evolution of teaching practice (Sandholtz, Ringstaff & Dwyer,

Figure 1. Research model

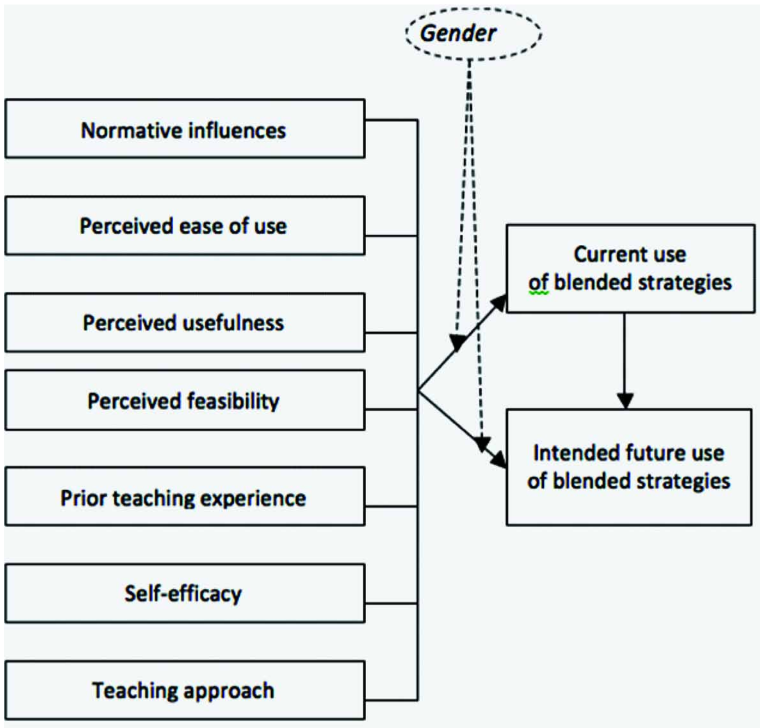

Figure 2. Conceptual framework elements and the precipitating predictor constructs of the theoretical model

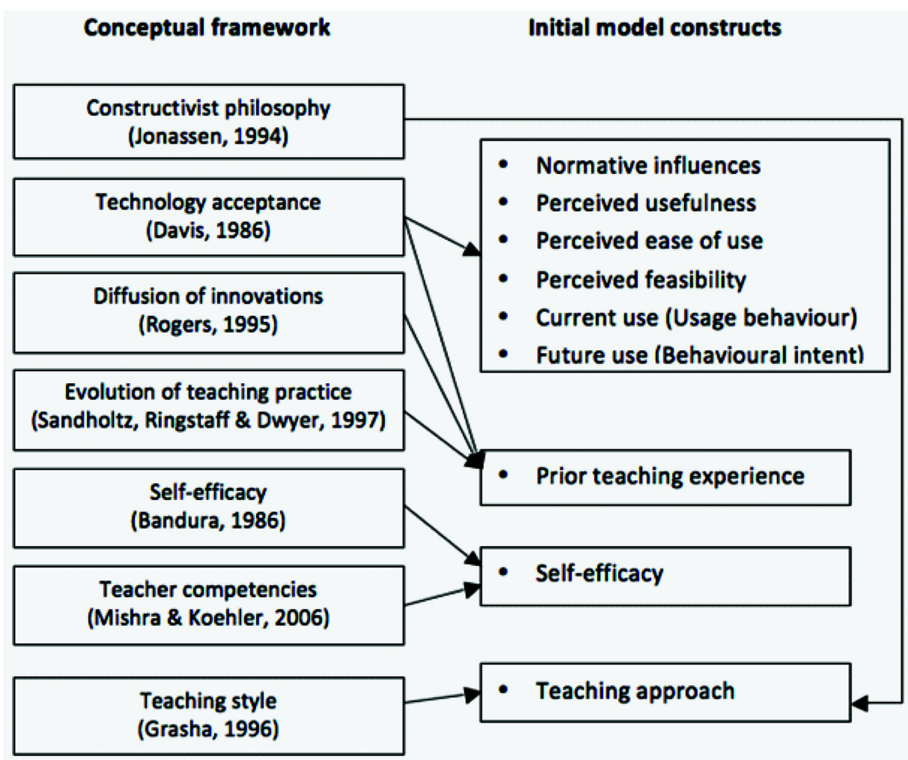

1997) self-efficacy (Bandura, 1986) teacher competencies (Mishra & Koehler, 2006) and teaching style (Grasha, 1996). Figure 2.0 shows each of the model's predictor constructs and the conceptual framework element/s from which the construct emerged.

Each of the predictor constructs in the research model will now be defined, and relevant literature supporting the inclusion of the construct in the model will be briefly considered.

Normative Influences

Normative influences refer to an individual's belief about whether people important to them think that the behavior should or should not be enacted (Fishbein & Ajzen, 1975). Prior research on the acceptance of technology has investigated the role that normative influences play in academics' acceptance of technologies (e.g., Chang Lieu, Liang, Liu & Wong (2011); Tarcan, Varok, & Toker (2010)).

Important to the concerns the present study is identifying those groups whose opinions one might expect to be important to academics. Literature related to professional support of academics shows that supervisors and peers may be two such important groups. For example, Chew, Jones and Blackey (2010) report on the implementation of online assessment as an institutional strategy at the University of Glamorgan and found that having senior university staff members using blended strategies had a generally positive influence on the uptake of blended learning by more junior faculty members.

The large volume of blended learning literature concerned with the student opinions of blended strategies (e.g., Mitchell & Forer, (2010; Salmonson & Lantz, (2005; Richardson & Turner, 2000) suggests that students are another significant group whose opinions are important to academics.

Perceived Ease of Use

The amount of effort an academic believes he or she needs to expend to implement teaching strategies that require the use of both technology and face-to-face teaching is captured by the perceived ease of use construct. Existing literature on technology acceptance points to perceived ease of use as being a significant influence on the acceptance of technology (e.g., Halawi & McCarthy, 2000; Kripanont & Tatnall, 2009). The present study explores the role perceived ease of use may play in how technology is used.

Perceived Usefulness

Perceived usefulness is a core construct of the technology acceptance models. In technology acceptance models perceived usefulness positively affects behavioral intention to use technology. For the present study, perceived usefulness is the degree to which academics believe that using technology together with face-to-face teaching strategies will enhance teaching effectiveness. Researchers such as Halawi and McCarthy (2010), Chang et al. (2011) and Tarcan, Varol and Toker (2010) have found perceived usefulness positively influences the intent to use technology. Perhaps then, perceived usefulness may also significantly influence how the technology is used.

Perceived Feasibility

Present in some technology acceptance models (Venkatesh & Bala, 2008), feasibility is considered to influence usage behavior. Feasibility conditions such as time, infrastructure, professional support, technical support, and funding have been found to be significant in influencing academics' acceptance of technology (e.g., Bagher, Marek & Sibbald, 2007; Davis & Fill, 2007; Kistow, 2009; Ocak, 2010; Stewart, Bachman, & Johnson, 2010;

Wang, 2009). Given that implementing blended approaches generally requires a significant investment of time and resources, it is likely that academics' perceptions of feasibility conditions such as time, funding, support, and infrastructure play a role in shaping the extent to which technology is used by academics in their teaching.

Prior Teaching Experience

Sandholtz, Ringstaff and Dwyer (1997) observe that teachers using technology tend to progress through a number of stages of technology usage with increased experience in teaching with technology. Experience as an influence of usage behavior has also been identified in the technology acceptance models described in the previous chapter.

Self-Efficacy

Self-efficacy is the belief in one's capacity to succeed in an undertaking (Bandura, 1986). Within the present study self-efficacy refers to academics' belief in their own ability to implement teaching strategies, in a specific content area, using both technology and face-to-face teaching. The construct of self-efficacy in this study has been framed in terms of the technology, pedagogy, and content knowledge framework (Mishra & Koehler, 2006) which suggests that for teachers to use technology effectively they must possess technological, pedagogical and content knowledge

Self-efficacy in this study is conceptualised in terms academics' beliefs about their ability to:

- Use technology (technical knowledge);
- Design effective teaching strategies (pedagogical knowledge);
- Understand course content (content knowledge);
- Make good decisions about teaching approaches appropriate to teaching the content (pedagogical-content knowledge);
- Identify which technologies can be used in the content area (technological-content knowledge);
- Understand the attributes of the technology and how they can be used to form new teaching strategies (pedagogical-technological knowledge);
- Identify the attributes of technology as well as design new strategies using those attributes to best teach the required content knowledge (technological-pedagogical-content knowledge).

Teaching Approach

Aligned with Grasha's (1996) conception of teaching style, the 'teaching approach' construct is used in the present study to refer to the characteristic manner in which individual teachers design the instructional process. The decision to use teaching approach as a predictive construct is made on the observation that, in some existing studies, constructivist teaching approaches were found to be conducive to using technology as an intrinsic part of learning activities (Judson, 2006; Grasha, 1996; Weitkamp, 2006).

METHOD

This study uses a two-phase approach to data collection. In the first phase, gathering quantitative data took place through the use of an online survey instrument designed specifically for the study. The survey link was distributed to Griffith university academics via email. A door-to-door paper survey was also used in attempt to boost response rates. A total of 53 academics responded to the survey.

The survey included the following components:

- Demographic information - gender, faculty, class size, number of years teaching in/outside of higher education.

Figure 3. Matrix for measure of current use of blended strategies

Indicate the extent to you use technology with face-to-face teaching to do each of the following:	
Address areas in which students experience difficulty	Not at all Extensively 1 2 3 4 5 6 7
Achieve course objectives.	Not at all Extensively 1 2 3 4 5 6 7
Present ideas in different ways.	Not at all Extensively 1 2 3 4 5 6 7

Develop innovative strategies.	Not at all Extensively 1 2 3 4 5 6 7

Actual current use of blended strategies matrix (Figure 3) - The matrix enabled academics to select the extent and purpose of usage of face-to-face strategies, and the extent and purpose of usage of various technologies. The list of technologies was created using the tools available in Learning@Griffith (Learning@Griffith is Griffith University's teaching and learning management system). The measure of *current use* of blended strategies for each respondent was obtained by converting each academic's selections in the matrix to a single score by allocating weightings to purpose and extent of usage for each technology, and then summing the scores for each technology used.

Seven, 7-point Likert Scale items to measure *intended future use* of blended strategies (Figure 4) -enabled respondents to indicate the extent to which they would like to use technology to achieve certain practice objectives in their nominated course.

- Twenty-seven, 7-point Likert Scale items to measure normative influences, perceived ease of use, perceived usefulness, perceived feasibility, prior teaching experience, self-efficacy and teaching approach. The twenty-seven items were selected from an initial pool of thirty-one items by using the Q-sort method. The Q-sort method as described by Nahm, Solis-Galvan, Rao, & Ragu-Nathan, (2002) was used as a simple yet effective method of assessing construct reliability and validity.

The item sets are shown in Table 1. Respondents were asked to indicate their level of agreement with each item (1 – strongly disagree through to 7-strongly agree).

In the second phase, semi-structured interviews were conducted. A subsample (N = 8) of survey respondents was interviewed. The selection of interview participants was based on the quantitative results. Outlier sampling was used to purposefully select interview participants from the pool of survey respondents willing to participate in interviews. The qualitative data yielded from the interviews was used to add depth to the understanding of the quantitative findings.

QUANTITATIVE FINDINGS

Before regression could be performed on the predictor construct data that was collected via the items shown in Table 1, instrument reliability needed to be addressed. Instrument reliability was demonstrated by undertaking item analysis of each of the construct item groups, that is, item analysis was conducted to check that each item, in the each set, was a good measure of the construct it intended to measure (Colten & Covert, 2007; De Vaus, 2002; Hair, Black, Babin & Anderson, 2010). Two values were calculated: Cronbach's alpha and the corrected item-total correlation. Cronbach's alpha is a check to see if all the items that intend to measure the same construct produce a similar score. Hair, Black, Babin and Anderson (2010) recommends that the lower limit value of Cronbach's alpha is 0.6. The item-total correlation checks if any item is inconsistent with averaged

Table 1. Items used to measure of predictors of current and intended future blended strategy

Constructs	Item
Normative influences	Many of my peers believe academics should use technology together with face–face teaching.
	Students have the expectation that I will use technology together with face-to-face teaching
	Industry expects students will study courses that use both technology and face-to-face teaching.
	The university would like academics to use technology together with face-to-face teaching
Perceived ease of use	It does not take much effort to use various technologies together with face-to-face teaching.
	When I use technology for teaching I do not worry that things will go wrong.
	It is easy to match characteristics of various technologies to core content, ideas, and skills.
Perceived usefulness	Technology together with face-to-face teaching is useful for enriching students' learning experiences.
	I find technology together with face-to-face teaching is useful for increasing students' opportunities for discussion and collaboration.
	Technology together with face-to-face teaching is useful for increasing efficiency.
Perceived feasibility conditions	The available professional support allows me to use technology together with face-to-face teaching
	Teaching facilities allow the possibility of using technology together with face-to-face teaching
	I have enough time to use technology together with face-to-face teaching
	The technical infrastructure of the university makes it possible to use a variety of technologies in my face-to-face teaching
Self-efficacy	I can see how I can use technology combined with face-to-face teaching to implement strategies appropriate to the course objectives.
	I am confident in my ability to include technology in teaching to enhance how I teach and engage students.
	I am confident I can solve my own technical problems.
	I am able to select effective teaching strategies to guide student thinking.
	I have good, up to date knowledge of the content area.
	I can use a wide range of teaching approaches.
	I can identify specific technologies suited to understanding the content in my content area.
Teaching approach	I use group discussions to help students think critically about content.
	I guide students' work by asking questions and exploring options.
	I encourage students to generate their own notes.
	I encourage students to restructure their existing knowledge in terms of new ways of thinking.

Table 2. Construct means across all study participants (N = 53)

Construct	Mean
Perceived usefulness	5.58
Perceived feasibility	4.81
Self- efficacy	5.40
Current use score	7.20
Future use score	5.42
Perceived current use score	4.61
Number of years teaching experience in higher education	13.31 years

behavior of other items in the group. The minimally accepted value of the item-total correlation is 0.3 (De Vaus, 2002; Hair et al., 2010).

Upon analysis, all items met the minimum value of 0.6 for Cronbach's alpha. However, an inspection of item total correlations lead to the removal of the normative construct item: "industry expects students will study courses that use both technology ad face-to-face teaching" because its value of 0.252 is less than the minimally acceptable 0.3 (De Vaus, 2002; Hair et al., 2010).

With item analysis complete, and the reliability of the instrument established, data analysis could begin. The means for construct scores across all 53 respondents are given in Table 2.

Regression was undertaken for constructs as predictors of 1) *current use* of blended strategies, and 2) *intended future use* of blended strategies. The resulting model parameters for *current use* of blended strategies are given in Table 3.

The positive estimate coefficients in Table 3 indicate a favoring of the use of blended strategies. Those academics with high perceived usefulness scores are predisposed towards using blended strategies in their current practice (note the positive coefficient). On the other hand, the negative coefficient for teaching experience in higher education indicates academics that have been teaching in higher education longer are pre-disposed to lesser use of blended strategies.

A particularly interesting outcome is the presence of interactions with gender. In particular, there is a *self-efficacy: gender* interaction and *a perceived usefulness: gender* interaction. The positive coefficient for the *self-efficacy: gender* interaction indicates females with higher self-efficacy with regard to the use of blended strategies are more inclined to use blended strategies in current practice. The negative coefficient of the *perceived usefulness: gender* interaction indicates that for female academics perceived usefulness is not as important influence on the use of blended strategies as it is for male academics.

Table 3. Model parameters for current use of blended strategies

Fixed Effects

Self-efficacy: Gender = female	4.82572	1.80222	2.678	0.0103 *
Perceived usefulness: Gender = female	-3.36219	1.55028	-2.169	0.0354 *

Significance codes: 0 *** 0.001 ** 0.01 * 0.05 . 0.1 ' ' 1

Table 4 gives the resulting model parameters for *intended future use* of blended strategies.

An examination of Table 4 shows perceived usefulness is a highly significant predictor of the *intended future use of blended strategies*. The coefficients of both perceived usefulness and current use are positive indicating academics who perceive blended strategies as useful are more likely to use blended strategies in the future, and those academics who are currently using blended strategies are also more likely to use blended strategies in the future.

Interestingly, perceived feasibility has a negative coefficient. This is seemingly counter-intuitive in that it suggests that those academics that perceive blended strategies to be more feasible are less likely to use them. One possible explanation can be arrived at by firstly, noting that perceived feasibility interacts with gender and the *perceived feasibility: gender = female* interaction has a positive coefficient, thus female academics who perceive the task as highly feasible are more likely to intend to use blended strategies in the future. Secondly, observe that perceived usefulness is of greater importance for male academics' for *current use* of blended strategies than it is for female academics. Possibly, for male academics, perceived usefulness is the primary concern and they will tend not to use blended strategies, even if feasible, unless they are perceived as useful.

Finally, normative influences are not significant but trending towards having a positive influence on the *intended future use* of blended strategies.

The resultant models are visually represented in Figure 5.

The quantitative outcomes will now be discussed in light of interview data so as to enrich understanding.

DISCUSSION

Quantitative analysis revealed perceived usefulness as a significant predictor for the use of blended strategies. For male academics especially perceived usefulness is a significant predictor of *current use* of blended strategies. Perceived usefulness was found to be a highly significant predictor of *intended future use* of blended strategies for both male and female academics. Given its significance, the concept of perceived usefulness warrants some discussion. During interviews a distinction emerged between perceived usefulness for the purpose of teaching and learning versus perceived usefulness in terms of administrative efficiency or ease of access. It became abundantly obvious that when academics view the use of technology with face-to-face teaching as useful for enhancing learning, it is a strong driver for the use of blended strategies. Those academics with high perceived usefulness scores acknowledged usefulness of technology for purposes of efficiency and flexibility, but most importantly placed emphasis on use targeted towards enhancing learning experiences. For example, one participant (perceived usefulness score= 7, current use score =10) noted that blended learning is "a marriage of tech with face-to-face making it the best learning outcome". Another participant (perceived usefulness score = 7, current use score = 20) explained her integrated use of technology with face-to-face teaching in terms of learning activities and teaching:

I upload previous student essays and get them to mark them and explain why so they engage in discussion about this [discussion boards]... I also use online case studies linked to book chapters and question banks. It's very integrated...I found it [technology] very useful ...as we move through the course I see them [students] challenging each other…The online discussion feeds into the face-to-face teaching and learning.

In contrast, those academics with lower perceived usefulness score focused on efficiency and access and neglected the learning experience in their comments. One participant (perceived usefulness score 4.8, current use score=0) felt that technology was "nothing more than an administrative device". Other participants with low perceived usefulness scores and low current use scores expressed a similar sentiment:

Recording lecture audio is useful for students to access" (perceived usefulness score =4.6, current use score =2);

My main motivation for using [technology] is that we have a large cohort of students … that way I don't need to use the board as much and I use the internal communication thing on Blackboard (perceived usefulness =5, current use score =0).

An interesting feature of the resulting models for both *current* and *intended future use* of blended strategies is the presence of gender differences in the significant constructs. In the predictive model for *current use* of blended strategies, gender differences exist for the predictive constructs of perceived usefulness and for self-efficacy. Perceived usefulness is a significant predictor of current blended practice adoption for male academics but not so important for female academics. Self-efficacy, on the other hand, is more important as a predictor of *current use* of blended strategies for female academics. These quantitative outcomes manifested in interviews. Female academics placed emphasis on feeling confident and having the required skills. For example female academics made comments such as:

I've got the skills and if don't have the skills then I take the time to learn to do them ..., if it's too difficult or complex then I don't bother;

I'm pretty new here, it's a constant battle to find out what I can do and what's available and how to use it… I feel quite comfortable doing stuff once I find out;

I'm still learning...things go wrong. If things go wrong I use the tech person, he's very good. If I can't get him I use my colleagues who also have those skills so it's no problem.

An important observation is that although female academics elaborated in some detail on self-efficacy and technical support, the three male participants did not raise the issue of self-efficacy and support but rather focused almost exclusively on usefulness:

You shouldn't use it just for those reasons anyway [efficiency]. I mean I it is something you can do better with technology? That's really the question (male academic).

In the predictive model for *intended future use* of blended strategies, gender differences are observed with respect to perceived feasibility. Perceived feasibility is a significant predictor of the intention to use blended strategies in the future for female academics but not so for male academics. The emphasis that female academics put on feasibility during interviews supports the quantitative result. In addition when female academics discussed feasibility, the issue of time was often raised:

My focus is student-centric, make it fun, engaging, keep my students, I'm prepared to do what it takes… I make the time (Female; perceived usefulness = 7, perceived feasibility = 6.5);

Any plans I have for the future involve more work for me – that will require a lot of extra effort and time. There's lots of things I'd like to do, but I need to draw the line somewhere (Female, perceived usefulness=6, perceived feasibility= 3.7).

In relation to time, female academics frequently identified professional support as a mechanism to reduce time investment:

Again it's time, if someone would come to me and say well here's all your options that'd be great (Female, perceived usefulness =6.4, perceived feasibility 2.3).

In contrast, male academics made brief mention of time, and when they did it was only in reference to technical failures leading to loss of time:

Technology has 'gotten in the way' of student engagement to a certain extent, fiddling and messing around can slow you down, equipment can fail and nothing happen, so it has risks; in terms of a lecture does it really make you do more, I don't think so (Male, perceived usefulness=4.6, perceived feasibility=4.0).

The remaining significant predictor constructs present in the models are teaching experience as a predictor of *current blended practice,* and current practice as a significant predictor of the *future* intention to use blended strategies. Understanding of both these predictors is also enhanced by discussion in light of interview data.

With respect to the teaching experience predictor, it was found that the greater number of years teaching experience in higher education were less likely to be currently using blended strategies. Interview data added an interesting perspective to this finding. The participant with the greatest number of years (38 years) teaching experience viewed the use of technology in teaching as being in competition with traditional face-to-face teaching – a question of which is better:

Is it [technology] better than carefully planned face-to-face teaching … Can it be shown that bringing in technology is going to improve the learning experience? (perceived usefulness score =4.8, current use score=0).

In contrast those with the least teaching experience considered if the use of technology was appropriate to certain situations making comments such as

you've got more options [using technology with teaching]"; "this subject can't really be taught any other way…if it was a different subject then there would be more that could be done with the technology

The importance of current practice as a significant predictor in the predictive model for *intended future use* of blended strategies, was clearly demonstrated during interviews. As the model predicted, those with positive experiences in their current practice are more likely to use blended strategies in the future, whilst those negative experiences 'put academics off future use':

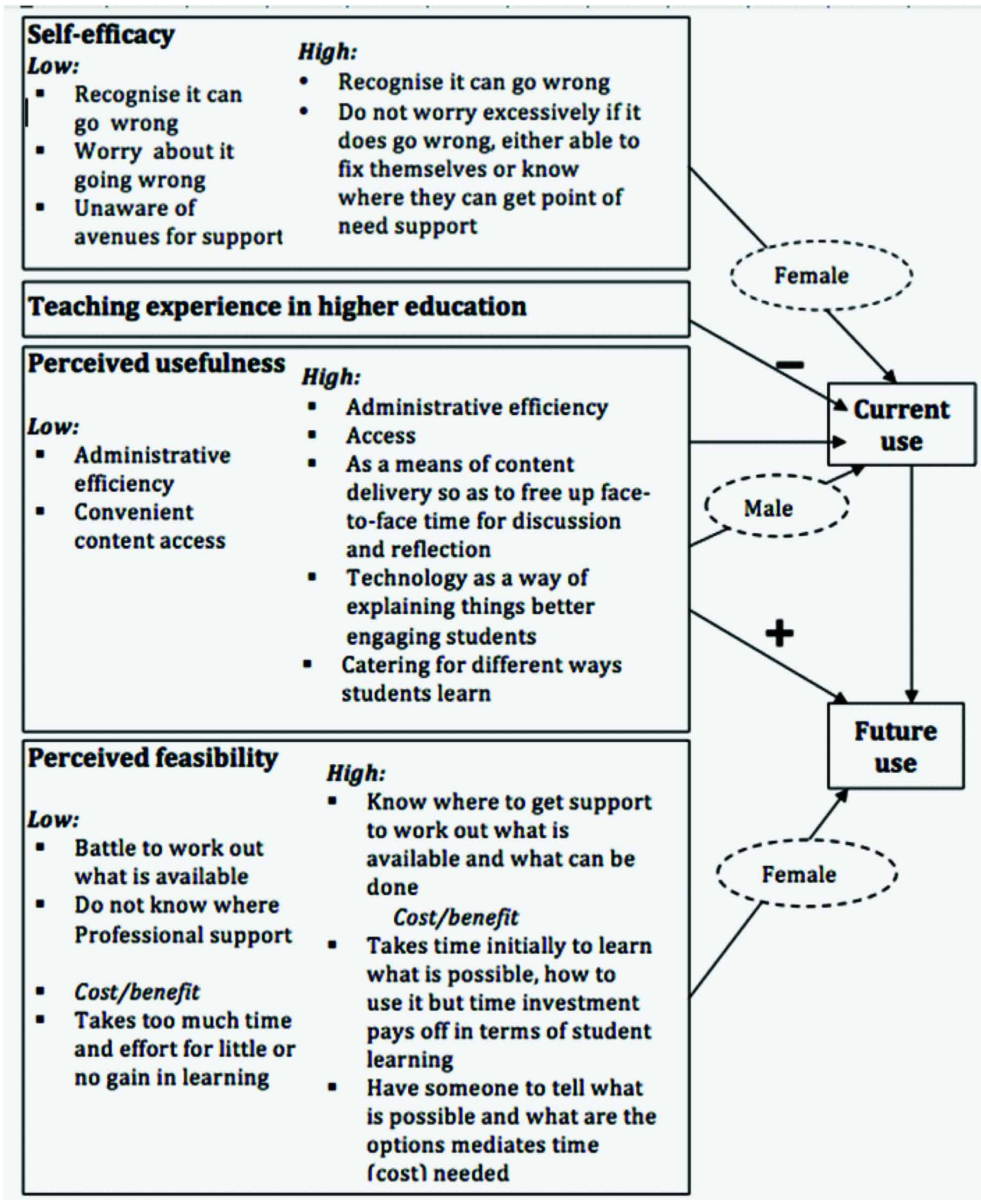
I upload case studies and ask them to respond to that..[in another course] I upload previous student essays and get them to mark and explain why so they engage in discussion about this…I've found it [discussion boards] quite useful...I use them in another course [with case studies] (Female, perceived usefulness=7, current use score=20, future use =6.2);

I don't use discussion boards [anymore]...they [students] just used them to complain or ask when marks were coming out or things like that… I have used online quizzes. It worked but it wasn't that useful because they'd [students] sit in the library [with] a set of computers. One was Googling and the other be doing the test (Female, perceived usefulness=6, current use score=4, future use = 5.3);

I once borrowed a roving microphone to use with Lectopia. It was so complicated to use I never used it...Once [when the technology went wrong] I had to apologise to a large class. A lock up like that rips out lots of time"; "I've set up discussion groups...but students remained silent and didn't use them (Male, Perceived Usefulness=4.8, current use score=0, future use score=5.2).

A discussion of the quantitative results in light of interview data both supported findings and enriched understanding of factors shaping how academics use technology in their teaching. The most important insights from interview data are added to the theoretical model to give the enhanced model shown in Figure 6.

Figure 6 . The model enhanced by qualitative insights



RECOMMENDATIONS

By expanding understanding of factors influencing how academics use technology, the present research sought to contribute to the body of knowledge that informs the formulation of professional support and development. From the research findings three key recommendations for professional support may be made:

Emphasis on pedagogy not on the technology.

Perceived usefulness was found to be a significant predictor of current and *intended future use* of blended strategies. Perceptions of usefulness of the use of technology with face-to-face teaching that related to improving student learning (and not just efficiency and flexibility of access) were most conducive to the use of blended strategies.

This finding has implications for the manner in which workshops and other support is provided. Professional support should not be techno-centric and focusing on technology. Rather a pedagogical perspective should drive support activities. It would be useful if professional support relationships with academics began by mapping learning objectives to the strategies and technologies that are currently being used. Using the information recorded in the mapping forms the basis for discussion about what strategies are working and what improvements or changes are needed.

Professional development initiatives must consider gender differences.

The research has uncovered the existence of gender differences related to self-efficacy and perceived feasibility. It is therefore important that those supporting academics' blended learning efforts are made aware of these differences. For female academics, greater self-efficacy increases the likelihood of current blended strategy use, and increased perceived feasibility raises the likelihood of the intent of using blended strategies in the future. Clearly self-efficacy and feasibility are important considerations for all academics, but professional support for female academics should incorporate specific strategies to target these constructs.

It is critical that those involved in supporting academics are made aware of the existence of gender differences so that blended learning support initiatives can be designed to address the differences between genders especially with regard to self-efficacy and perceived feasibility.

For female academics, greater self-efficacy increases the likelihood of current blended strategy use, and increased perceived feasibility raises the likelihood of the intent of using blended strategies in the future. Although self-efficacy and perceived feasibility are necessary considerations for professional support for all academics, for female academics, professional support should give more direct attention to increasing self-efficacy and perceived feasibility. Given also the emphasis on support by female academics it is imperative that measures are put in place to both provide the necessary support and disseminate information about where to get support. Professional development activities such as workshops etc. should be followed up by arranged contact with appropriate technical support individuals in order to establish contact before support is required in practice. A 'buddy' system maybe particularly useful in which academics are paired with colleagues who possess greater technical knowledge and are thus able to provide support also.

With respect to feasibility, female academics identified the provision of support as resulting in a reduction of time investment. It is recommended that professional support staff, from initial contact, work together to identify best options for a particular teaching context rather than simply giving a general 'showcase of available technologies'. In this way, preparation time is greatly reduced because relevant options are considered.

Seek to gather knowledge about the current practice of the academics they are supporting, and use that knowledge to provide appropriate support.

The importance of academics' current practices with the use of technology with face-to-face teaching was made evident by the results of the present study. Current usage was found to be a highly significant predictor of the intent to use blended strategies in the future. It is recommended that there is a focus on understanding academics current practices and it is considered important to gain insight into prior experiences of using technology. Information about current practice may be collected during workshops and serve as a launching point for more individualized support later.

Limitations and Future Directions

Whilst the study has expanded understanding of factors that influence how academics use technology after adoption and led to some recommendations for provision of more effective professional support for academics, the study limitations must be acknowledged before concluding. The limitations potentially restrict the generalizability of results but also direct attention to further research. In the described study, limitations relate to sample size, sample acquisition, institutional culture and context, and the limited number of constructs investigated.

It is unknown if a larger sample size would yield different results. Furthermore, research participants voluntarily chose to participate suggesting they were already interested to some degree in the use of technology for teaching. Results may have been influenced by this attitude.

The study was conducted within one institution in which there is strong strategic focus on blended learning and has implemented a plethora of support mechanisms for academics. Griffith University's focus on blended strategy may influence academics use of blended learning. Griffith University is a large multi-campus university situated in Australia and the results of the study may not necessarily generalize to institutions of different scales in other countries. The need for cross-cultural studies of a similar nature to this study is self-evident.

An extension of the present study may consider how disciplinary difference impact on the predictive model. A longitudinal study tracing the development of blended strategy use and any changes in perceptions in individual academics over a period of time would also be an interesting extension to the study. Finally, the study was limited to seven factors. Human behavior is very complex. Thus a natural extension of the study would be to consider a wider range of potential predictors.

CONCLUSION

The study endeavored to increase understanding of factors shaping how academics use technology in their teaching practice by identifying a predictive model of current and *intended future use* of blended strategies. Applying regression techniques to data collected via a survey from 53 Griffith University academics yielded some interesting insights. In the initial research model it was proposed that: (1) academics' disposition towards using blended strategies in their current practice could be predicted by seven constructs (perceived usefulness, perceived ease of use, perceived feasibility, teaching approach, feasibility, teaching experience and normative influences); and (2) academics intention of using blended practices could be predicted by the same seven constructs along with current practice. Subsequent data collection and analysis has shown that not all of the seven proposed predictor constructs were significant predictors of *current use* of blended strategies, and *intended future use* of blended strategies. Perceived usefulness, teaching experience in higher education and self-efficacy were significant predictors of *current use* of blended strategies. Perceived usefulness, current use and perceived feasibility were significant predictors the intention to use blended strategies in the *future*. For both *current* and *intended future use* of blended strategies gender differences exist among the factors predictive of the use of blended strategies.

The study makes a contribution to understanding why academics are inclined to use technology to create blended strategies while others do not. Importantly, it has been established that the academics' experiences, perspectives, and gender are important factors shaping how they use technology for teaching, and worth investigating further.

Chapter 6
Benefits of the Flipped Classroom Model

Marie Larcara
Canisius College, USA

ABSTRACT

With the advent of new technologies and the move for faculty to implement these into their teaching practice, a new model for course design and delivery has developed called the flipped classroom model. As more instructors investigate this model, the benefits, which include classroom management, active learning, critical thinking, and maximum use of student-faculty time together, become obvious. With classroom sizes increasing, more instruction moving online, and resources dwindling, the flipped classroom model can be an improved model for both instruction and quality learning. Research supports the benefits of the flipped classroom, but the change from a traditional classroom model to a flipped model requires a pedagogical shift on the part of both teacher and learner.

INTRODUCTION

There's a reason so many have latched on to the concept of the flipped classroom. And, there is a reason many K-12 teachers have moved, or are moving to this model. As early as the nineties, Nancy Atwell (1998) wrote about the reading/writing workshop. This method, at the time, was not called "flipping," but it most certainly follows what later teachers came to define as a flipped classroom (Bergmann, 2013). The workshop method asks that teachers essentially watch students read and write in class, using mini-lessons as the basis for teaching, rather than period-long lectures (Atwell, 1998). When I begin teaching in 1993, the workshop method and "flipping" were not on my radar. I didn't realize it at the time, but I was a constructivist, believed strongly in student choice whenever possible, and embraced the idea that students need to connect on a personal level with the content for it to move into their own world. Many of us have a story to share of our early teaching experiences, and I am no exception. I was an adult when I returned to earn my teacher certification. As a newly certified high school English teacher, I felt confident in my skills. Unlike my peers in education classes, I did not suffer the learning curve with time management, organization, lesson planning, or classroom management. One of my first assignments was a long-term

DOI: 10.4018/978-1-4666-8246-7.ch006

substitute middle school language arts classroom where I was informed I was the third teacher that year. I came in to the situation in April, with just about three months of instruction time left in the year. I was told the class was "troublesome" but not given many details beyond that. After more than one violent outburst, and a situation that had to involve many parents, social workers, and the school psychologist, I realized this class needed something different. There was daily violence, little respect for each other or me, and more than a few students at risk of failing. Reaching out to a mentor, it was suggested I look into Atwell (1998) and a reading/writing workshop method. Of course I did not know it, but this was to be my first experience with a flipped classroom. In my dog-eared, coffee-stained copy of *In the Middle* (Atwell, 1998), the author begins the text with these words:

These days, I learn in my classroom. What happens there has changes; it continually changes. I've become an evolutionist, and the curriculum unfolds now as my kids and I learn together. My aims stay constant-I want us to go deep inside language, using it to know wand shape and play with our worlds-but my practices evolve as eighth graders and I do deeper. This going deeper is research, and these days my research shows me the wonders of my kids, not my methods. But it has also brought me full circle. What I learn with these students, collaborating with them as a writer and reader who wonders about writing and reading, makes me a better teacher-not great maybe, but at least grounded in the logic of learning, and growing. (p. 3)

What Atwell is telling us here, years before we named it "flipping," is essentially that we must work and learn *with* our students, not *at* them if we are to grow as professionals and put their learning at the forefront of our teaching practice. This was transformative for me as a new teacher and I dove in.

As I quickly realized that the traditional classroom management strategies I had learned in college would not help in this unique situation, and with the added incentive of landing a permanent teaching job, I devoured my copy of *In the Middle* (Atwell, 1998). In the book, Atwell uses the art of storytelling to teach us a method of classroom instruction, which, even now, seems foreign and quite a paradigm shift. It involves differentiating instruction, individualized learning, choice, and new and challenging management strategies. While Atwell did not have the benefit of the emerging technologies we do today, she was in fact "flipping" her classroom. In a reading/writing workshop classroom you watch students *do* something with the content. They collaborate, peer revise, talk out loud like writers and thinkers, and process their learning in front of the teacher and peers. The teacher, in Atwell's early days, used intense, "mini-lecture" format to deliver new content. You do this by daily assessing the learning needs of the group and addressing them in intense, shorter teaching formats. Today, these may be a video created to address a specific need of the group or a part of a lecture students traditionally struggle with. But, the bulk of class time is not spent talking *at* students; instead, the classroom is an active learning environment in which the teacher is a guide. This requires a shift in both pedagogy and skills which many find intimidating. I know I did, but the move from a passive classroom environment to an active one transformed me as a teacher and I still refer to and think of Atwell often.

If you could see my copy of *In the Middle* right now, you would see a desperate, new teacher's scribbles in the margins. Some read, "NEVER do this again" or "ALWAYS use this as a journal" as a way of making sense of my own teaching philosophy and her stories. But, beyond Atwell's stories, she also shares research and explains that, coming up with the reading/writing workshop method, among other strategies she shares, is the result of a shared experience between the teacher and students, changing with every shift in student and content, resulting in "theory in action" (p. 22). This collaboration between the teacher and students and the action they take together to "forge and inhabit a common ground where the logic of their learning and my teaching can finally converge to become one" (p. 22) creates the philosophy and drives the methodology. It is with this attitude I suggest you investigate the "flipped classroom" -for there is not one way to tackle this strategy, one way to make it work, or one method that guarantees success. Instead, it is another tool in the teacher's toolbox to enhance the teaching and learning process and build a "theory in action" which can impact both teacher and learner as they continue to grow.

Asking teachers and faculty to create a more active classroom is not new and research has shown that students at all levels can benefit from an active learning format. From college professors aimed at improving content literacy (Butler, 1992; Garfield, 1995; Sander et al., 2000; Smith, 1998) to the K-12 classroom (Walker, 2012) those who aim to improve the student experience are adding active learning and flipping the classroom as a strategy for learning. From positively impacting retention (Schullery, Reck, & Schullery, 2011) to improving motivation (Strayer, 2012), the flipped classroom clearly has many benefits.

Teachers and Students Flip

Bergmann (2013) ask that those who consider flipping their classroom ask themselves one essential question, "What is the best use of face-to-face time with students?" (Stop for a moment and reflect on that.) If one answers that question honestly, and from a student-centered perspective rather than a teacher-centered perspective, the answer must be that the best use of face-to-face time with students is creating products, having students demonstrate and practice new learning, asking questions to deepen learning, and participating in peer review and revision with the goal of a better product. I would venture to say that few would answer that the best use of time with students is going over what students were *supposed* to read, or reading verbatim the slides of a PowerPoint presentation. But that has been, and still is, the method used in many classrooms. In short, in a flipped classroom, student time is active, not passive. The passive activities of reading and listening to lecture are saved for online or at home time. Class time is reserved for clarifying, extending, re-directing, and creating a product or project utilizing the new content. It is active, questions are raised and addressed, new content is framed in experience, and students can use high-levels of Bloom's Taxonomy-yes even in our technological age-to show what they know (Munzenmaier, & Rubin, 2013).

This requires a new set of skills for teachers and a new set of behaviors for students, which may seem insurmountable at first, particularly for those struggling with covering the massive content required in many subjects. But, that said, teachers from Kindergarten to the doctoral level, even those in very heavy content areas, are embracing this strategy to enjoy the benefits of added motivation, deeper learning, authentic assessment, and student success. Teachers aiming to flip their classrooms and create an active environment must begin with planning and aligning activities to learning goals (Biggs & Tang, 2007). This process may be new to some, or by the nature of changes to curriculum and teaching assignments, may require time and energy, as well as collaboration, to put in place. If a teacher has not re-visited their program and course goals and objectives, and aligned them with assessments, there is work to be done. A tightly constructed curriculum, which scaffolds learning from week to week and course to course, can result in meeting program goals, but this alignment takes collaboration and effort both at the onset, and in re-visits as curriculum, teachers, strategies, tools, and students change. Once done though, the move to active rather than passive learning can re-invigorate the teaching and learning process. According to Pierce and Fox (2012):

The challenge for educators in every discipline is for them to transition from being dispensers of facts to being architects of learning activities. Critical in this process is designing experiences that facilitate students developing into active learners rather than passive receptacles of information.

In many institutions, class sizes are increasing and traditional resources are shrinking, yet emerging technologies and more equal access to the Internet are giving teachers more high-quality online content. Along with new developments in how people learn and acquire new content, the more traditional large lecture delivery method is coming into question (Pierce & Fox, 2012). Teachers who decide to flip their classrooms can and often do create original material. But, that said, there are also well-respected educators who are creating content to be shared. From EdX, to Coursera, to The Khan Academy, to Massive Open Online Courses (MOOCS), content is being made available which can be used and shared to enhance learning. While some argue the quality of this content, and not all available content is credible or good, each day there is more and more high-quality, relevant, useful content available to teachers. The list of possible added content seems endless as more and more embrace the open and sharing content philosophy. This includes well-respected educational institutions and professors including Harvard Open Courses (http://www.extension.harvard.edu/open-learning-initiative).
Need a visual or more creative way to help struggling students understand the water cycle? Do a search on teachertube and you can find a rap version of the water cycle ("The Water Cycle Rap," 2011). Want to offer students the chance to extend their learning on a subject of particular interest? Visit the Harvard Open Course: Open Learning Initiative and search the available topics. While some argue that open content is the disruption of education (Bass, 2012), classroom teachers are also finding these sources to be invaluable as they create and curate more and more content to address diverse learners and allow for active instruction time.

Moving to a more active classroom also requires planning for a tightly constructed curriculum, which ties learning outcomes, activities, and formative and summative assessments. Taking this plan and delivering it in a flipped model means moving the focus to what a student *does* with the new content. This can even include students teaching and coaching other students (Berrett, 2012), a model which is often a paradigm shift for the traditional teacher. But, the rewards of this paradigm shift are many and leaders are looking closely at this model as a way, not only to make large classes more productive, but also as a way to better measure student learning and use this information to create better learning, and more effective management of resources for learning (Berrett, 2012). Fulton (2012) notes that the shift in thinking about managing the classroom from a traditional teacher-focused classroom to a flipped classroom can be a struggle for teachers. Teachers must use video or other technology to re-invent the lecture and staying ahead of that proves difficult for some (Fulton, 2012).

Similarly, classroom management skills must be honed, as students are no longer passive. This requires a renewed purpose for teaching, but also a review, or learning of advanced classroom management strategies. Managing group work, answering student questions, utilizing formative assessment methods, helping students learn how to learn actively, are all required in this model. So, why go through all this change? The impact of increasing student motivation, of watching students *do* something with the content, and addressing all students' learning can transcend the teaching and learning process. For example, the implications for those who struggle with reading and low performance due to low-level reading can lead to poor attitudes for learning and school in general, negatively impacting a student's future and success (Davis, Spraker, & Kushman, 2004). Watching and re-directing students in the process of learning can be improved before assessment, thus breaking this negativity and cycle of failure.

This empowers students and often helps those who have had little or no success in the classroom before, find that success.

Silver, Strong, and Perini (2007), note "Research and experience demonstrate that teaching strategies are critical to the overall health of the classroom and to the academic success of our students (p. 4). By improving instructional strategies, diverse learners can be addressed and learning improved. This approach, which is also a process approach in many ways, breaks down the large tasks and helps the individual meet those tasks in a process approach-ensuring success. Aiming instruction towards the individual learner, rather than to a whole group, is often called *differentiating instruction*-a strategy, which can improve content literacy (Chapman & King, 2009).

- Differentiation is when a teacher modifies instruction in one of four ways:
- Offering different content;
- Offering a different process of learning the material;
- Offering a different product to apply or extend what is learned; or
- Offering a different environment for learning to address the individual learner (Tomlinson, 1999).

Examples of differentiating content include using varied reading materials (by content or by difficulty), allowing the reading to be done using technology (audio), using paired reading strategies, or using small group instruction when needed. To differentiate by process, one might use tiered activities, which means presenting the same skills or concepts, but utilizing different levels of complexity or support. To differentiate the product, an instructor might offer choices in how a student or group proves learning. This may include a formal paper, a presentation, the use of multi-media, etc. Tomlinson (2004) shares examples of differentiating by environment to include:

Making sure there are places in the room to work quietly and without distraction, as well as places that invite student collaboration; providing materials that reflect a variety of cultures and home settings; setting out clear guidelines for independent work that matches individual needs; developing routines that allow students to get help when teachers are busy with other students and cannot help them immediately; and helping student understand that some learners need to move around to learn, while others do better sitting quietly.

While Tomlinson is speaking here of the elementary classroom, we know that even adult, high-level students can benefit from differentiating in these ways. For example, differentiating environment in a college classroom may involve having a learner or group move to a quiet spot to work on their research or project. This move may be important for learners who learn better on any given day in a quiet space.

In a flipped classroom, differentiation is possible-some would say necessary. Firstly, the online lectures can be audio and written. This already addresses differentiation as students can listen to the lecture as often as they like, which can benefit many students, specifically those dealing with content which is difficult for them. Students can refer back to the lecture later in the semester, when studying for a final exam, or when working on a project. The ability to read and hear a lecture multiple times truly addresses differentiation and learner needs. The teacher can also differentiate the flipped classroom content. Projects can be based on student interest, students can work in groups of their choosing, and while watching and listening to students' work, the teacher can differentiate based on obvious student need and interest. This level of instruction required daily reflection on the learner and practice and a set of management skills which may be new to some.

In a flipped classroom, the teachers have the ability to check in, monitor, re-direct and mentor the individual at each class meeting. This will allow for an in-depth knowledge of each learner on a level which may be new to the traditional teacher. We know that integrating learning styles and multiple intelligences into the classroom can positively impact the learning process (Silver, Strong, & Perini, 2000). To properly address diverse learners (intellectual, physical, and cultural), requires a deep understanding of the way students think, problem-solve, learn, process, and create new information. It also required both teacher and student to share lived experiences as they relate to the new content. This creates the active classroom where the teacher guides rather than delivers learning and where students and teachers are, in Atwell's words, working together to "forge and inhabit a common ground where the logic of their learning and my teaching can finally converge to become one" (1998, p. 22).

Teachers can quickly learn to create lectures and helpful videos, which can be housed online. New and even free technologies are being created which make this is a relatively simple task (see Jing and apps such as "Explain Everything, and "Screenchomp," and "Educreations"). Where the creating of video in the past was involved, costly, and created a need for technical support, today technology tools are often free and intuitive enough that virtually any instructor can create video on their own. In fact, as flipping is taking hold in education, faculty are realizing they can collaborate on the creative of videos and even share content (Ash, 2012). This is not only saving time, but also creating opportunity to collaborate, which can improve curriculum alignment and research opportunities. Once past the learning curve to do so, video can be quickly created and stored for use from semester to semester. Think of how much MORE teaching can be done with the time usually spent on lecture given to direct interaction with students! While the up-front time to create these, and the learning curve to do so, may involve a learning curve for many teachers (Fulton, 2012), the benefits for both teachers and students are many. Also, as companies develop emerging technology, and as institutions more fully embrace open resources, there are more and more content videos available for free and open use. Not without controversy, the Khan Academy was influential in both the movement to flip and in providing open content for teaching and learning, and others are taking on the charge to make available open content.

One benefit for teachers, once they free up class time, is the ability to facilitate deep discussions, watch students participate in small groups, allow time for writing and projects, and organize activities to synthesize the learning. These in-class activities may include debates, panel discussions, student-led presentations, peer revision, and other active learning strategies. Rather than delivering content to students in the form of lecture, the teacher can watch, observe, note, and re-direct learning as students engage with the new content. A very important element and benefit of this model is that the teacher in a flipped classroom watches the students perform or participate; therefore they can redirect the learning when a student misunderstands the content. For example, if there is a class discussion, or student-led panel discussion, the teacher can interject and offer new examples or information for clarity and depth of learning. Often times, in this model, students will also jump in and offer excellent examples, which may help their peers to understand the new content and tie content to students' lives, which also improves learning (Chapman & King, 2009).

For students completing the work at home, with no supervision or mentorship, the opportunities for re-direction are minimal. Only when the teacher grades the homework or written work, can redirection happen. Often, this is either too late (post-assessment), or the feedback is not of the quality to help the student deepen their learning. Minimally, this passive feedback, often in the form of written feedback on written assessment, may never be applied or scaffolded to the next level of learning and the teacher still does not have the face-to-face opportunity to clarify. If the student does not understand the written corrections, or does not read them, there again is a lost opportunity for growth, which goes on to impact success as the teacher builds upon that content.

In summary, a wonderful benefit to a flipped classroom, and one, which is gaining importance of late, is the fact that you can fine-tune your assessments to the course and program objectives, utilize formative assessments along the way, and minimize failure on the summative assessment . In a traditional classroom, you cannot tell if an assessment is successful until you see the results. Often, this is too late for both the teacher and student. In a flipped classroom, students are showing you on a day-to-day basis what they know and how they are growing with the content. The teacher can still use formal assessments, and both formative and summative assessments, but the results are often easier to predict. Also, with watching learning in action, there are great opportunities for active research. A teacher can take a pre-assessment (survey, "ticket out the door," etc.), implement a strategy (literacy strategy, group discussion, etc.), the do a post-assessment to validate a teaching strategy. The time to do this is created in the flipped classroom and can transform the teacher's practice in many ways.

More and more, teachers at all levels are asked to document and utilize data to drive instruction, and opportunities to utilize action research is one way to impact this process (Marzano, 2003). Marzano, speaking of K-12 school reform but applicable to all levels, outlines the use of action research for reform to include three basic steps. First, take the pulse of your school (or in higher education department or program). This can include a questionnaire or survey to identify gaps or needs. Next, identify and implement an intervention. This can include a literacy strategy to improve learning, new assessments, direct observations, participant interviews, etc. Finally, examine the effect on achievement. Since the goal of any intervention is the positive impact on learning (Marzano, 2003, p. 166), this step is crucial. Collecting evidence is important to impact change and this stepcan include multiple teachers and leaders.

The flipped classroom model offers the opportunity to collaborate on such research, implement it, reflect upon it, and initiate positive change .In fact, the opportunity to reflect on the teaching practice in general can be positively impacted with flipping the classroom. Fichtman Dana and Yendol-Silva (2003) acknowledge that teachers have "an enormous amount of knowledge that they have accumulated through their years of teaching" and that "this knowledge can be mined by teachers studying their own practice, making visible the complexities of teaching" (p. vii). Through classroom and collaborative research in the active classroom, teachers can improve their own practice and student learning utilizing data rather than "only" instinct and experience. Fichtman Dana and Yendol-Silva (2003) explain, that,

Teacher inquiry differs from traditional professional development for teachers, which has typically focused on the knowledge of an outside "expert" being shared with a group of teachers. This traditional model of professional growth, usually delivered as a part of traditional staff development, may appear an efficient method of disseminating information but often does not result in real and meaningful change in the classroom. (pp. 5-6)

This holds true for teachers at all levels and has long been a complaint of K-12 teachers hungry to improve their practice, only to be forced to sit through a professional development which does not meet their needs, or offers no support for implementation. The use of action research, and collaborative opportunities for research which translates into action, can break this cycle, empower the teaching practice, and improve student learning. Fichtman Dana and Yendol-Silva (2003) finish their text by urging teachers to finish the practitioner inquiry model by making the inquiry public. This last step moves not only the individual teacher's practice, but can impact others as well. The authors make the analogy of unshared teacher inquiry to a stone lying beside the pond,

Unless that inquiry is tossed into the professional conversation and dialog that contributes to the knowledge base for teaching, the inquiry has little change of crating change. However, once tossed in, the inquiry disturbs the status quo of educational practices, creating a ripple effect, beginning with the teacher himself or herself and his or her immediate vicinity (the students and his or her classroom) and emanating out of a school, a district, a state, eventually reaching an contributing to the transformation of the perimeter of all practice-the profession of teaching itself. (pp. 139-140)

Again, while geared to the K-12 practice, this is relevant to higher education as well. In fact, in some ways, departments in higher educational institutions may need this opportunity as much, if not more, than the K-12 teacher. As teachers who are also asked to research in their field (not necessarily as it relates to teaching or student outcomes), college faculty often have little or no opportunity to refine their teaching or reflect and improve upon their practice.

In a flipped classroom, there is also the opportunity for the teacher to see great growth, and offer extension of learning to those who may desire it. A student who shines can be offered a different opportunity to deepen learning. This too is a way to address diverse learners in the classroom (Chapman & King, 2000). Examples of this might be to differentiate for that student by offering more or more detailed sources to investigate, or even a different product to prove learning. Asking a student to apply their project or paper to the real world, and report back to the class, is one example of how one can deepen and extend learning for the student in question, but also for the others in class. In a traditional classroom, it is much more difficult to recognize students who may excel in the content and who would enjoy a deeper experience. The flipped model, based on active and individualized instruction, offers teachers a chance to know their students' interests and gifts on a much deeper level, which can inform later project choices and support as students go into the field of their choice. To facilitate this, teachers can use class time to design learning experiences that include sources chosen or guided by students' individual interests and those they want to read (Moore, Bean, Birdyshaw, & Rycik, 1999). In the classrooms of today, this may involve emerging or "new" literacies (Lanksear & Knobel, 2003), including content texts in the form of blogs, online articles, videos, etc. Allington (2002), notes that an issue in classroom's today is that students cannot learn from texts they cannot read, therefore diversifying the choice in reading is key. This individualization and constructivist approach can greatly improve content area reading and literacy (Alvermann, Phelps, & Ridgeway-Gillis, 2007) and allow the teacher to reach both those who struggle, and those who would benefit from extension.

American students, for the most part, are not used to a flipped classroom-particularly at the college level. In some ways, they may be more comfortable at first with a traditional classroom. They can show up, sit quietly, and even "zone out" if they want and still receive credit for being present. But, once home, if they do not understand the content, there is little or no opportunity for help or redirection. In the flipped classroom, the ownership and responsibility for reading the material and listening to the lecture is put on the student. They will soon realize that the teacher is not going to go over all that was to be read or listened to in class and research shows that students embrace and respect this new classroom model (Butt, 2012). For some time now teachers have lamented that students do not read the material (Allington, 1977).

If you ask students why they don't complete the reading, the reasons are many. One common reason often given by students is that there is not a purpose for reading. Why read when the teacher will go over all concepts in class in a long lecture, often accompanied by a PowerPoint with ALL the information given on the slides? Without a purpose for reading, students may superficially read, skim, or skip the reading altogether. Or, for those who struggle with literacy, they may labor over the reading, but not truly comprehend the content. In a flipped model, if they do not show up with the reading completed, they will not be able to participate at the high level a flipped classroom model requires. With some guidance and patience, and some new classroom management strategies (rubrics, student choice in reading, problem-based projects, etc.), a teacher can quickly acclimate students to this model and the benefits are many (Johnson, 2013; Butt, 2012). When students are held responsible for their own learning, and they know they will have to show what they know during class activities, they will take the work more seriously. Their audience becomes authentic, because they will be working directly with their peers. This, along with other tools the flipped classroom teacher may utilize, such as student-led discussions, presentations, and projects, will require students to come to class prepared (Minifie & Davis, 2013).

Bergmann (2013) shares the experience of his daughter in a flipped high school classroom. She shares, "For the first time ever I had the ability to pause the teacher while watching the lectures online. Working on my own timetable allowed me to explore learning styles and techniques, and to hone in on the way that I learn best." She goes on to share that the flipped classroom also helped her feel in control of her learning and the added ability to "Step up and take responsibility for my own learning at a pace that worked for me." Finally, she shares how the flipped classroom alleviated stress (She is reflecting upon a college Chemistry class, mind you). She felts supported, even when she did not fully understand the content she completed at home, and knew that clarity would come in the risk-free, flipped classroom her teacher created. For more information from Bergman and others on flipped learning, visit the Flipped Learning Network Ning at http://flippedclassroom.org/video/navigating-the-flipped-learning-network-ning.

Another benefit of the flipped classroom is the opportunity for student-to-student modeling and students are often energized by this active opportunity (Bergmann, 2013). Since students are not sitting passively in class, they can listen to each other, share work with each other, peer revise and edit, and offer a fresh and different perspective on the content to their peers. Again, this is not possible or probable in a traditional lecture-based setting. It is well known that the classroom environment impacts learning, motivation, and engagement and that teachers need to provide a challenging and positive climate where all students can be successful. Those who struggle often lack self-efficacy and motivation for the tasks with which they are charged. Self-efficacy is impacted by past performance, vicarious learning, and physiological reactions, such as fear and anxiety (Davis, Spraker, & Kushman, 2004).

In order to enhance self-efficacy, teachers need to build learning environments and experiences, which allow for risk-free learning, and knowledge of the learner beyond their classroom identity. Only then will the learner gain self-efficacy and find their own competence that can then be transferred to the learning task (Hinchman, Alvermannm, Boyd, Brozo & Vacca, 2003). Taking an interest in students' outside of the classroom identity, and allowing peer to peer collaboration builds confidence and will lead students to take risks, and grow as learners. The collaboration of teacher to student, and student to student creates a high-achieving focus in the classroom and helps to cultivate a mutual respect for learners and the teacher. With the teacher as ally, students will take risk with content and push each other to achieve higher levels of learning (Brozo & Flynt, 2008).

While many picture a flipped classroom as online lecture and all collaboration happening in person, the online portion of the class can offer student-to-student interaction as well. The teacher can ask students to listen to a lecture, or other material (videos by experts), and then require them to participate in an online peer discussion on the topic.

Best practices here are that students are asked to help each other in the online discussion to see how the new content fits into their professional or personal lives. This peer interaction can be one of the most beneficial aspects of flipping the classroom. In the traditional classroom, students benefit little from each other in the class, and only connect outside of class if they make the extra effort to do so. But, in an online discussion, students can take their time to respond to one another, and with proper guidance and use of best practices, the instructor can nudge students to new levels of learning and response which utilizes high levels of critical thinking and resources.

Last but not least, a flipped classroom offers the opportunity for the teacher to have the in-class activities consist of parts of the assessment as a whole. For example, instead of assigning a research paper in the beginning of the term, then lecturing through the semester, reminding students of the paper here or there, in a flipped classroom, the classroom activities can BE the parts of the research paper. The students will listen to the lecture, and experience the resources (video, added readings, webinars, etc.), outside of class. Inside class, they can write and share sections of their papers, share high quality resources, or even collaborate on a section of the paper. They can peer review, share findings, discuss the importance of their research, debate their findings, defend their choices, etc. During this, the teacher is refining with them, helping them to see new connections, making suggestions, re-directing, and extending the learning. By the time the teacher sees the final product, they have experienced the pieces of the product more than once with the students and grading is much faster and easier. And, of course, if a student is not understanding the content, or not reaching the depths required, this can be corrected along the way-ensuring a high-quality, successful, end product. The chances of a student failing to gain mastery in this model is much less than in the traditional model of assigning the work to be done outside of class.

CONCLUSION

There is an art and science to teaching and teacher growth is necessary for one to improve their practice. Unfortunately, there may be little growth in the art of teaching in a traditional classroom. Teachers may revise their lectures and readings, based on student success on assessments, but beyond that, there is little feedback given to a teacher in the traditional classroom. In a flipped classroom, the "feedback" is visually apparent each and every class meeting. You can see and hear if students are growing as learners and you can make adjustments to your practice when it really counts-before the assessment and before the students give a final evaluation of the course! This built-in time to adjust can be quite transformative to a teacher and learner. A warning is given by Ash (2012) however, in that taking an ineffective teacher and asking them to flip their classroom will not result in success. According to Wolf (as cited in Ash, 2012), "You can't just hand the flipped classroom off to an ineffective teacher and say you're going to transform the classroom. It's not going to make a bad teacher a good teacher." It's more complex than that, but worth the effort to transform to reap the benefits for both the teacher and learners in the classroom.

KEY TERMS AND DEFINITIONS

Bloom's Taxonomy: A classification of educational objectives based on the work of Benjamin Bloom and a committee of educators in 1956. Educational objectives are divided into domains, including cognitive, affective, and psychomotor.

Differentiated Instruction: An instructional theory which takes into account diverse learners in planning, delivering, and assessing learning. Learning environments are varied by interest, delivery, abilities, and modes of assessment.

Flipped Learning: Learning where student-teacher interaction time is optimized. Often, lectures, readings, and passive activities are done outside of student-teacher time together.

Massive Open Online Courses (MOOCs): A way to deliver online content to any person interested in taking the course. There are no limits on attendance and the MOOC is often large, with many diverse participants.

New Literacies: A form of literacy, which came about due to digital technology and the access to text and images in new media formats.

Screencasting: The use of video for instruction. Lectures can be screencasted in video format so that students can access the lecture more than once, and refer back to it at a later time. Various technology tools are used to video the information.

Chapter 7
Promoting Active Learning through a Flipped Course Design

ABSTRACT

There are numerous ways in which faculty can deliver information in a blended course; however, the question remains as to which information is best suited to online delivery versus face-to-face. The focus of this chapter is on the flipped classroom, including a study in which a psychology statistics class was flipped and students' statistical knowledge, attitudes toward statistics, and intercultural sensitivity were assessed. In order to understand the theoretical underpinnings of the classroom, the authors examine the flipped structure through Blended Learning Theory, Problem-or-Project-Based Learning Theory, and Cognitive Taxonomy Theory. Advantages and disadvantages to transitioning to such a format as well as applications to other courses and some of the best practices in a flipped course are discussed.

INTRODUCTION

Colleges and universities across the country are utilizing distance learning, including online and blended course formats. This trend is not recent, in 2000-2001, 90% of 2-year and 89% of 4-year public institutions offered distance education options (Jackson & Helms, 2008). In 2005, 3.2 million students were enrolled in online courses (Callaway, 2012). Allen and Seaman (2011) conducted a large-scale survey of 4,523 active, degree-granting institutions of higher education in the USA. In conjunction with the Babson Research Group and the College Board, their analysis represents 80% of higher education enrollments. Results of the survey indicate that online enrol-

DOI: 10.4018/978-1-4666-8246-7.ch007

ment, as a percent of total enrolment has increased from 9.6 in the fall of 2002 to 31.3 in the fall of 2012. This equates to 1.6 million students taking an online course increasing to 6.1 million. The growth rate of 18.3% is larger than that of higher education overall, which has only grown at an annual rate of just over 2% during the same time period (Allen & Seaman, 2011).

After massive growth in online enrollment over the past 8 years, 2010 marked the first sign of slowing. Projections suggest this rate will stay steady over the coming years for all intuitions including public, private, non-profit, and private for profit (Allen & Seaman, 2011). Distance learning courses allow institutions to expand current student markets, increase brand recognition and the alumni base, while saving campus energy and operational cost. These courses have allowed institutions to battle cuts in state funding while recruiting students beyond their local or regional markets, thus enabling them to extend their brand nationally and even globally (Allen & Seaman, 2011; Betts, Hartman, & Oxholm, 2009). In addition, faculty training for online education can be an indicator for intuitional support. Only 6% of intuitions report no training for online teaching, a number that has significantly degreased over the past decade. The most common training reported includes institutionally run courses (72%) and informal mentoring (58%). Such training is provided at a higher rate than courses intended for face-to-face teaching (34%) (Allen & Seaman, 2011).

Distance learning courses not only benefit schools but they also match the majority of students' life-long experiences with the Internet. Current traditional age college students are described as "digital natives" who have always had laptop computers, cell phones, and text messages (Davis, Deil-Amen, Rios-Aguilar, & Canche, 2012). Distance learning courses allow students to maintain some autonomy over how and when they complete course requirements. Such flexibility has been found to be important for student satisfaction (Allen & Seaman, 2011; Callaway, 2012; Muirhead, 2002; Ocak, 2012).

Faculty perceptions of distance learning are also important. When polled, 44% of Chief Academic Officers of intuitions that offer online education say their faculty accepts the value and legitimacy of online education. This number has not changed much in the past 8 years (although it varies widely by school) (Allen & Seaman, 2011). In a recent study, 73 faculty members of various levels were surveyed on their perceptions of blended teaching (on-line and face-to-face), their satisfaction with such courses, roles, and perceptions of student learning (Ocak, 2012). The majority of faculty (88%) reported being generally satisfied with teaching blended learning classes. In addition, 92.1% reported their students learn a lot in the blended course. Ninety-six percent felt that blended courses were appropriate learning environments for college courses and that they were eager to teach another blended course (69.6%). However, it should be noted that 95% of respondents believed that blended learning requires more time and effort than face-to-face and full online course formats. They acknowledge that it requires creativity in teaching and requires educators to reflect in meaningful ways on their pedagogy. Few disadvantages were reported, such as problems with students' ability to use of technology and lack of intuitional support. Overall advantages of blended learning outweighed these issues (Ocak, 2012).

The high numbers of online and blended course enrollment indicate that distance learning is a viable and desired option for students. Furthermore, the majority of intuitions and faculty are in support of such course formats, especially in regard to blended learning. It is important to better understand the learning environments and student outcomes of courses utilizing Internet technology. To begin, a clear understating of what distance education courses are is of focus, with an emphasis on blended learning.

What is Blended Learning?

Traditional courses are face-to-face in which the majority, if not all, of content is delivered using methods inside of the classroom (Allen & Seaman, 2011). In an online course the majority, if not all, of the content is delivered via the Internet on course management systems (Allen & Seaman, 2011). A hybrid course combines online and face-to-face delivery where by any amount of content is delivered online, while the rest is delivered in a reduced number of face-to-face class meetings (Allen & Seaman, 2011; Jackson & Helms, 2008).

As a point of clarification, hybrid courses are often called "blended learning environments" (Howard, Remenyi, & Pap, 2006; Osguthorpe & Graham, 2003). However, Blended learning implies mingling together in ways that lead to a well-balanced combination, uniform, and harmonious mixture (Osguthorpe & Graham, 2003). Osguthorpe and Graham suggest there are at least three elements that an instructor might blend together in a course including:

- Online and face-to-face activities,
- Online and face-to-face student meetings, and
- Online and face-to-face instructor and student meetings.

The goal is to create a synchronous set of learning activities where classroom based face-to-face interactions with instructors and peers is complemented asynchronously by work performed outside of class. Typically in these situations there is a lack of immediacy in feedback, assessment, and the instructor's ability to work collectively with students. Modern learning technologies make it possible to provide what is missing here, adapting the learning to each individual (Osguthorpe & Graham, 2003). For the purpose of this paper we will adopt Garrison and Kanuka's (2004) definition of blended learning stating, "at its simplest, blended learning is the thoughtful integration of classroom face-to-face learning experiences with online learning experiences" (p.96).

Howard and colleagues (2006) suggest that integration is an important aspect of blended learning. In an integrated-blended learning environment the student studies online before class, works on material during class meetings, and then revisits material again after class online. In this model, the student can prepare before class by taking online pre-tests, utilizing resources (e.g., readings or online lectures), and participating in adaptive exercises. During class, the student interacts with peers and the instructor, works to clarify content, and receives feedback. After class, the student can perform more online exercises, revisit concepts, and take online post-tests (Howard et al., 2006).

Some educators posit that blended learning courses, such as the model described above, offer the best of both delivery methods (Rausch & Crawford, 2012). It is proposed to minimize some of the weaknesses of fully online courses by allowing face time with the professor, student, and peers, and provides an opportunity for clarity of difficult concepts or assignments (Bersin, 2004; Lage, Platt, & Treglia, 2000). Offering courses in such a mixed format can be a one-course-for-all system that shifts the course from a professor-dominated to a student-centered world (Chamberlin, 2001). However, not all researchers agree. Some suggest that blended courses are stuck-in-the-middle, being neither effective in teaching methodology nor low-cost for intuitions (Callaway, 2012; Jackson & Helms, 2008). In addition, results from survey data suggest, "there is a lack of consistency among students and faculty as to what is the most effective and innovative way to design hybrid courses" (Callaway, 2012, p. 15), leading to the need for more research to better understand what materials are best delivered online versus in-class (Brothen & Wambach, 2007; Masalela, 2009).

What is Flipped Learning?

Flipped learning, also called a flipped classroom, utilizes blended learning to reorganize the structure of a typical classroom model. The reorganization centers on inverting when and where students complete course work and are exposed to content via lectures. “Inverting the classroom means that events that have traditionally taken place inside the classroom now take place outside the classroom and vice versa” (Lage et al., 2000, p. 32). In this way, a flipped classroom employs blended learning by using the Internet to deliver content to the students, frequently assigning lectures to be viewed online while students are away from school. When students come into the classroom they have already been exposed to the lecture content and can immediately start working on assignments and course related material.

The motivation for flipping a classroom stems from the problems that can exist within traditional in-class lectures. Lectures are often passive, and provide a “one-way flow of information from professor to the student” (Foertsch, Moses, Strikwerda, & Litzkow, 2002, p. 26). Professors who employ active learning techniques argue that timing is the biggest issue with lectures. Using class time to lecture takes up valuable minutes that students and professors have to interact with each other and the material. However, lectures are a necessary aspect to college teaching. Professors have a level of expertise that students need to be able to comprehend the material under investigation. Even professors that use active learning pedagogy often find it necessary to convey specific knowledge by giving lectures before group activities can begin (Foertsch et al., 2002). Flipped learning can overcome this paradoxical problem. It allows professors to still delver content using lectures but saves class time for important course work and interactions.

With the prevalence of blended courses, and some inconsistency in the literature about their effectiveness, this chapter will work to provide professors with an example of a flipped classroom, including data analysis of student learning and attitudes. We will describe a statistics course that used blended learning techniques to create a flipped classroom. Under the umbrella of active learning, this chapter will base blended and flipped classroom designs in three theories, Blended Learning Theory, Project Based Learning and Cognitive Taxonomy Theory.

THEORETICAL FOUNDATIONS

Just as it is important to investigate and review the research on flipped classrooms, it is also important to contextualize this research within a theoretical framework. In order to understand the theoretical underpinnings of the classroom, we suggest future researchers and practitioners who wish to implement the flipped classroom should consider the explications that Blended Learning Theory (e.g., Alonzo, Lopez, Manrique, & Vines, 2005; Kerres & De Witt, 2003), Problem-or-Project Based Learning Theory (e.g., Helle, Tynjälä, & Olkinuora, 2006), and Cognitive Taxonomy Theory (e.g., Bloom, 1956; Krathwohl, 2002) provide. These theories may be considered to be under the umbrella of Active Learning Theory (e.g., Poirer & Feldman, 2007; Warren, 2006). As such, both the description and application of theory within the flipped classroom research is discussed.

Blended Learning Theory (BLT)

Description

BLT is a pedagogical approach to instruction that is a combination of face-to-face, computer mediated activities, and online learning that is rooted in Active Learning Theory (Alonzo et al., 2005; Kerres & De Witt, 2003). Kerres and DeWitt contend that BLT includes “….didactical methods (expository presentations, discovery learning, cooperative learning, etc.); and delivery formats (personal communication, publishing, broadcasting, etc.)" (p. 103). Osguthorpe and Graham (2003) suggest the term BLT to better represent the "mingling" of online and face-to-face best practices. BLT is proposed to minimize some of the weaknesses of full online courses by allowing face time with the professor, student, and peers, and provides an opportunity for clarity of difficult concepts or assignments (Bersin, 2004; Lage et al., 2000). Offering courses in such a mixed format can be a one-course-for-all system that shifts the course from a teacher to learner-centered focus (Chamberlin, 2001). Clearly BLT should be applied to the research investigating the efficacy of the flipped classroom, as it was a theoretical precursor.

Application

If BLT is an integral part of the flipped classroom as purported (Rausch & Crawford, 2012), how then, can it explain the results of flipped classroom research? First, Walker, Cotner, and Beermann (2011) investigated the impact of a modified flipped classroom had on student learning in a large basic biology course. Walker et al. used "vodcasts" and other multimedia methods to teach both online and face-to-face. After controlling for several individual demand characteristics, they found that students in the flipped classroom academically outperformed students in a traditional class format on some academic measures and were statistically the same on other academic measures. We suggest through the use of various Active Learning methods, computer mediated activities, and face-to-face activities, students in Walker et al.'s study were able to do as well as or even better than a more traditional lecture base course because unlike a traditional classroom, using BLT, the professor had more in-class time to achieve these techniques (i.e., active learning).

Project Based Learning Theory (PBLT)

Description

PBLT is thought to be student-centered pedagogy that focuses on a project or problem that is experienced by the students as means for instruction (Helle et al., 2006). Further, Adderley (1975, p. 1) defined PBLT as:

1. Involving the solution of a problem; often, though not necessarily, set by the student himself;
2. Involving initiative by the student or group of students, and necessitate a variety of educational activities;
3. Commonly resulting in an end product (e.g., thesis report, design plans, computer program and model);
4. Work often goes on for a considerable length of time;
5. Teaching staff are involved in an advisory, rather than authoritarian, role at any or all of the stages—initiation, conduct and conclusion.

Often in PBLT, the student learning objectives are directed at helping students develop intrinsic motivation, collaborative skills, flexible and effective problem solving skills, and ultimately self-directed learning (Hmelo-Silver, 2004). Additionally, PBLT provides students with the opportunity to solve real-world problems. The teacher is often viewed as a facilitator who works side-by-side with student to assist in framing questions and structuring authentic and meaningful tasks while providing critical feedback to the students (Hmelo-Silver, 2004).

Not only has PBLT been well defined, it has been successfully used in many contexts. Whether it was employed to enhance writing instruction English Language Learners (Foulger & Jimenez-Silva, 2007), or designing k-12 science instruction (Polman, 2000), or incorporating PBLT in technology (Boss & Krauss, 2007), PBLT has been demonstrated to be an effective means of instruction. Accordingly, when investigating the efficacy of the flipped classroom pedagogy, PBLT may be used to understand the potential theoretical underpinnings of the pedagogy.

Application

What would the view of the flipped classroom look like through the lens of PBLT? For example, Schullery, Reck, and Schullery (2011) found that students in a high-enrollment flipped classroom were more satisfied and engaged in the class as a result of the design. This was especially important as prior to the study, they found that the size of the class prohibited meaningful activities and discussions. The results of the Shullery et al. study may be interpreted through PBLT as Schullery and colleagues designed their pedagogy so that "students are encouraged to interact during discussions and they are expected to collaborate with their peers in classroom teams" (p. 3). We believe that this is analogous to one of the definitions and goals of PBLT in that students work together in collaboration to solve a joint problem (Adderley, 1975; Hmelo-Silver, 2004).

Yet another example of PBLT in the flipped classroom research occurs in a study by Pierce, Fox, and Dunn (2012). Pierce et al. used the flipped classroom pedagogy to teach renal pharmacotherapy in an 8-week course. They found that students both objectively outperformed and positively viewed the classroom when compared to a traditional lecture based class. One of the pedagogical tools used in Pierce et al.'s study was, in group settings, "design experiment…set in the messy situations that characterize real-life learning" (p.196). We believe this element and many other elements in the Pierce et al.'s study constitutes PBLT, in that the class was framed in a meaningful and authentic manner as suggested by Hmelo-Silver (2004). These are just a few examples of how PBLT can explain the research currently being conducted on the flipped classroom.

Cognitive Taxonomy Theory (CTT)

Description

Building on the works of Bloom (1956) and Anderson and Krathwohl (2001), Krathwohl (2002) modified the original Bloom's Cognitive Taxonomy to reflect current changes in the cognitive psychology literature. CTT is a way to categorize and identify types of cognitive processes. In other words, it is way of classifying thinking. Anderson and Krathwohl identified the revised CTT as pertaining to six cognitive domains (e.g., remembering, understanding, applying, analyzing, evaluating, and creating). These cognitive domains are hierarchical in nature and start with *remembering* (the most basic level) and end with *creating* (the most complex and highest level). Simply, *remembering* is defined as retrieving recognizing; *understanding* is classified as constructing meaning through processes such as summarizing; *applying* is implementing or executing a procedure; *analyzing* is breaking a concept into parts and understanding the interrelationship and structure among the parts; *evaluating* is making a criterion and standard based judgment; and *creating* is putting or reorganizing elements together into a new structure (Anderson & Krathwohl, 2001). CTT has been used successfully in countless research articles and is one of the most widely accepted and cited works in educational research today (Anderson & Sosniak, n.d.). Finally, we believe that CTT is a logical fit to understanding the research on flipped classrooms, as there CTT elements in the flipped classroom format.

Application

There are many ways in which we can apply CTT to flipped classroom research. CTT can directly be applied to the works of Pierce et al. (2012) and Sadaghiani (2012). First, Pierce et al. targeted the application level of CTT and found that when compared to a traditional classroom, students in a flipped classroom, significantly academically outperformed on application level assessments. We contend, that it is also likely that if Pierce et al. looked at other levels of CTT, that the students taught in a flipped classroom would demonstrate higher academic performance over that of direct instruction. Theoretically, the reason students did better at the *application* CTT level is because the instructional format enabled students to build lower-order CTT levels through self-regulated learning and thus process information at a deeper level. In another study investigating the effects of flipped classroom, Sadaghiani (2012) found that when students received online pre-lectures (i.e., podcasts and prequizzes), then completed problem-solving tasks in a face-to-face setting, students' physics knowledge increased, as did their enjoyment of the class. Sadaghiana's results can be explained by CTT in that as a result of the flipped classroom pedagogy, students built lower levels of learning (prior to class) and engaged in higher levels of learning during class using the flipped model.

LITERATURE REVIEW

The theoretical descriptions of PBLT, BLT and CTT set a framework for both blended and flipped learning paradigms. Such courses have the potential to offer the best of online and face-to-face teaching. Therefore, in this section we will discuss both the advantages (e.g., preparedness and engagement, student interaction, active learning, etc.) and the perceived disadvantages and barriers (e.g., technical problems, student perceptions, and lack of control) discussed in the literature on flipped and blended classrooms.

Advantages

Preparedness and Engagement

Faculty and students note that blended courses help students prepare for face-to-face classes, which helps increase engagement in the class as well as with course materials. Having students view the lectures online before coming to class allows them time to digest the material and be better prepared for higher level learning through in class applications (Gecer & Dag, 2012). Similarly, students report that online learning requires them to take greater responsibility for their learning (Gecer & Dag, 2012), which aids in developing independent scholarly skills. In addition, the better-prepared students are, the more likely they are to engage in the classroom (Schullery et al., 2011). For example, the online format allows students time to reflect on the material and their learning, which has shown to increase engagement and participation in the classroom (Dengler, 2008; Rausch & Crawford, 2012; Stacey & Gerbic, 2007). Students have commented on how online discussions help them to be concise and clear in their arguments and writing (Dengler, 2008; Stacey & Gerbic, 2007). Similarly, students who are hesitant to participate in class can use online discussion forums as a means to dialogue about class content, which can increase confidence to participate in face-to-face discussions (Rausch & Crawford, 2012; Stacey & Gerbic, 2007). Dengler (2008) suggests this might especially be the case for women and non-native English speakers.

Student Interaction

The benefits of increased student interaction and engagement are vital to building a sense of community in the course (Schullery et al., 2011). Incorporating online learning tools allows for more student collaboration as well as teacher-to-student interaction (Osguthorpe & Graham, 2003). Faculty note the transition to blended learning resulted in more time with students to facilitate learning (Beck & Ferdig, 2008; Schullery et al., 2011). Students also asked more questions in the online environment, including those related to their interests versus just class content (Beck & Ferdig, 2008). Others note how online discussion boards are frequently used by students to get help on topics and/or assignments with which they were struggling (Cole & Kritzer, 2009; Heinze & Procter, 2006). In addition, the blended format can offer more opportunities for group work. As a result, students learn to appreciate peer feedback and collaboration (Groves & O'Donoghue, 2009; Strayer, 2012).

Active Learning

Online tools can be used to have students engaged in the material beyond the classroom, which can aid in applying the material learned as well as add continuity between classes (Dengler, 2008). Faculty report an increase in critical thinking and independent scholarly skills through such engagement (Masalela, 2009; Osguthorpe & Graham, 2003). Even prerecorded lectures can be more of an active learning tool when students engage in the video by stopping to take notes, replaying points of confusion, and by using the videos for review (Foertsch et al., 2002; Senn, 2008). In the comparison of blended courses with traditional courses, students note the need to participate more actively in courses with the blended structure, which promotes learning (Gecer & Dag, 2012).

Flexibility and Interests

Students and faculty have also found the blended course format to allow for more course flexibility for students. For example, some faculty allow students the option to make the course completely online as long as they meet certain grade criteria (Ackerman, 2008; Brothen & Wambach, 2007). This gives students the opportunity to learn on their own time and in ways that best suit their needs (Masalela, 2009), which students report as a motivational factor in blended courses (Gecer & Dag, 2012). Students have also noted that they spend more time focused on the material when they can control when and where they learn versus having to sit in a classroom (Stacey & Gerbic, 2007). In addition, non-traditional students are better able to fit these courses around work and family (Osguthorpe & Graham, 2003). Zapatero, Maheshwari, and Chen (2012) suggest the use of technological learning tools also better meets the interests of younger students who are bored with traditional classroom methods. They note this boredom can lead to less engagement in the classroom and poorer student performance.

Diversity Inclusion

Although some may worry the blended classroom comes at a cost to content coverage, many faculty report coverage is not sacrificed (Lage et al., 2000; Osguthorpe & Graham, 2003). Instead, we found the format allowed for greater content coverage and application, including the infusion of diversity related materials. The need for a diversified education grows with our increasingly multicultural society (Hussey, Fleck, & Warner, 2010). In our rapidly changing and 'shrinking' world, researchers have reported greater awareness of White privilege, empathy for racial minorities, and increases in positive attitudes toward minorities when diversity was included in the curriculum (Hussey et al., 2010; Niehuis, 2005; Paoletti, Segal, & Totino, 2007). For example, Hussey and colleagues compared learning outcomes and attitudes toward minorities in a traditional course versus a diversity infused course. Diversity content was infused through such things as reading materials, class discussions and activities, and guest speakers. At the end of the semester, the courses did not differ in regards to content knowledge gained, but they did in terms of attitudes toward minorities. As will be discussed, diversity content was infused into the curriculum of the current study through "application days" and the final project.

Perceived Disadvantages and Barriers

As Mortera-Gutierrez (2006) notes, resistance of some level is expected of faculty for which online teaching is new. Some faculty might be better suited to blended learning than others based on their teaching methods and their openness to new teaching methods (Beck & Ferdig, 2008). Also, based on teachers' experiences with online learning tools, they might be more apt to perceive certain disadvantages or barriers to using a blended format. These potential disadvantages or barriers include technical problems and knowledge, student perceptions, lack of control, and mixed perceptions, each of which is described in detail.

Technical problems and knowledge: Faculty may avoid the use of online teaching tools for fear of technical problems, which can detract from learning and take away from class time (Mortera-Gutierrez, 2006). Non-adopters of blended learning note the importance of online infrastructure available at their school as well as technicians influencing their decision to transition to a blended format (Masalela, 2009). Relatedly, faculty may also avoid the use of online learning tools if they do not feel confident in their knowledge of using the tools effectively (Cole & Kritzer, 2009; Mortera-Gutierrez, 2006). This barrier could also be perpetuated if faculty feel they do not have time to learn about the tools or if they feel they do not have technical support in using the tools (Mortera-Gutierrez, 2006). Similarly, faculty may not feel they have the skill set to train students to use online tools.

Student perceptions: A number of potential barriers also exist regarding student perceptions of faculty and the course. Many students are accustomed to traditional courses and having access to their instructor while in class working on assignments (Foertsch et al., 2002). This is not always the case in an online environment. Unless the instructor is having online office hours, students will have to email questions and wait for a response, which could lead to perceptions of less faculty support in a blended course (Senn, 2008). This perceived lack of support can lead students to feel the blended course is more work. Although the workload is usually the same, Senn (2008) suggests such perceptions can arise from the effort students need to put into completing online assignments. For example, when students are in class, the instructor can see where students are getting stuck and provide immediate feedback. In a virtual class, it might not be as obvious to faculty where students are having trouble and feedback usually takes longer (e.g., email). In the meantime, students often search for the solution and become frustrated.

This frustration can arise from students not understanding the material to confusion over how to use an online tool. Not all students are computer savvy, which can lead to having to teach students how to access course material. This may include a training session at the beginning of the course as well as throughout the course as needs arise (Groves & O'Donoghue, 2009). Even after going through the online portions of the course, students can still struggle to access the material due to things such as internet connection issues, remaining confusion, or being overwhelmed by the amount of information provided (Gecer & Dag, 2012). However, addressing these issues early in the course will help students become comfortable with the technology and troubleshooting problems (Cole & Kritzer, 2009).

As a result of these potential issues, faculty might be hesitant to transition to a blended format due to possible negative student ratings. This might especially be a concern for faculty whose tenure and promotions hinge partly on student ratings (Cole & Kritzer, 2009). Students who struggle with the independent learning of the blended format, and in turn perform poorly, may blame this on the instructor and give lower course evaluation ratings (Senn, 2008). High expectations of faculty performance and the course structure can also lead to negative ratings (Gecer & Dag, 2012).

Lack of control: Faculty may be hesitant to transition to a blended course because they perceive having less control in the classroom. For example, the question arises as to whether students will actually view the online materials. Foertsch and colleagues (2002) found that most students watched prerecorded lectures in order to prepare for face-to-face classes. Others have used incentives to ensure engagement with online tools, such as allowing students to have input on certain course elements (Groves & O'Donoghue, 2009). To best incorporate online learning tools, faculty should also be aware of, and involved in the discussions students have online. This includes potentially unfamiliar territory, examples, and questions raised by students that faculty might not feel prepared to handle as these online discussions carry over into the classroom (Dengler, 2008). Heinze and Procter (2006) note that the use of online discussion boards can also be unpredictable due to students going off topic, not participating, or over-participating.

Mixed perceptions: Sometimes the elements of blended courses are perceived as both advantages and disadvantages. For example, Jackson and Helms (2008) examined students' perceptions of quality hybrid courses using a method that allowed students to identify what they perceived as important course elements. Students reported interaction with faculty as strength and a weakness of blended courses. For example, the online format allowed more time to reflect on answers, but also limited interaction with faculty, which could lead to perceptions of decreased learning. Similarly, interactions with other students was seen as an advantage and disadvantage because students felt they could learn from their peers in online discussion forums, but at the same time felt less connected to fellow classmates. Students reported the greater amount of work outside of class contributed to more in-depth coverage of material in class as well as critical thinking. However, others felt the blended format detracted from learning because students were able to read others' answers online before posting their own.

Time commitment is another factor that has been viewed both positively and negatively. Like any course, there are time commitment issues with prepping for a flipped classroom. However, the flipped course is more frontloaded in preparation than a traditional course due to setting up the virtual classroom, prerecorded lectures, and other materials (Cole & Kritzer, 2009). However, pulling from previous course materials as well as enlisting technical support can help reduce this workload (Lage et al., 2000). Faculty who are completely new to online teaching might benefit from training (Kim & Bonk, 2006), yet faculty might perceive this as intimidating or a burden (Cole & Kritzer, 2009; Masalela, 2009). In addition, faculty may worry about the added time of having to train students to successfully learn online (Masalela, 2009). Some faculty have also noted greater communication demands with students after transitioning to a blended format (Beck & Ferdig, 2008; Senn, 2008). This can lead to faculty frustration in feeling that student questions could have been quickly addressed during class conversations (Senn, 208). Furthermore, some faculty report increased feedback on assignments after switching to a blended format (Beck & Ferdig, 2008).

However, elements of blended learning can help increase learning with minimal time commitment. For example, many blended courses are developed from preexisting traditional courses, reducing the amount of work for faculty (Osguthorpe & Graham, 2003). Others have found that producing online lectures can cut lecture time in half (Foertsch et al., 2002). In addition, discussion board involvement for faculty might involve 30 minutes a week (Dengler, 2008). However, as class size increases beyond 40-50 students, time commitment will likely increase (Dengler, 2008; Lage et al., 2000). Nevertheless, there are instructors who use certain blended formats in order to increase student contact in the classroom to make the most of face-to-face time with their students in larger classes (Foertsch et al., 2002; Schullery et al., 2011). Other faculty have changed some assignments to be peer reviewed online versus faculty graded, which has also been shown to improve learning (Groves & O'Donoghue, 2009). In addition, this reduces faculty time commitment and students often report enjoying giving and receiving peer feedback (Groves & O'Donoghue, 2009; Jackson & Helms, 2008; Strayer, 2012).

Although there are a number of potential barriers to transitioning to a blended format, the benefits outweigh the costs (Cole & Kritzer, 2009). After faculty put in the time to learn the online tools and create the course, their time can be devoted to interacting with students and facilitating learning (Cole & Kritzer, 2009). There are also numerous strategies and best practices that faculty can employ in developing their blended courses to help with the transition, perceived barriers, and to increase student learning.

Best Practices for the Flipped and Blended Classroom

There are numerous ways in which faculty can deliver information in a blended course, however the question remains as to which information is best suited to online delivery versus face-to-face (Brothen & Wambach, 2007; Gecer & Dag, 2012; Masalela, 2009; Osguthorpe & Graham, 2003; Stacey & Gerbic, 2007; Strayer, 2012; Tao, Fore, & Forbes, 2011). Mortera-Gutierrez (2006) notes the most commonly used course elements in order of relevance include face-to-face meetings, reading assignments, self-paced content, online tools (e.g., discussion boards), video/audio conferencing, the virtual classroom, asynchronous instruction, and synchronous instruction. However, it is not enough to just randomly combine these elements (Tao et al., 2011), faculty need to be student-centered in their teaching methods (Beck & Ferdig, 2008). In other words, there may not be one format that fits all courses (Osguthorpe & Graham, 2003; Strayer, 2012). Some courses may require more face-to-face time than others, such as courses requiring more hands on demonstrations and practice (Beck & Ferdig, 2008; Senn, 2008). It is up to faculty to determine which blend is best suited to meet students' learning needs, with a focus on using the best methods from each delivery mode (Groves & O'Donoghue, 2009; Heinze & Procter, 2006).

Audio and visual materials: Faculty who use online audio and visual materials to help teach course concepts and/or to complement face-to-face material have found improvements in student learning (Mortera-Gutierrez, 2006). However, for such online learning to be effective, it is important that faculty educate themselves on this media and how to create and implement such online learning tools in order to help with ease of learning as well as to avoid lost class time (Mortera-Gutierrez, 2006). This includes aligning the use of online tools with course learning objectives (Groves & O'Donoghue, 2009; Strayer, 2012). In addition, faculty should help familiarize students with the online tools of the course and how they should use them to optimize learning. Heinze and Procter (2006) found such activities increase student online participation and depth of discussions.

Establish community and expectations: It is important to start the course with a face-to-face meeting in order to establish connections between students and faculty in order to create a sense of connection and foster interaction (Ackerman, 2008; Heinze & Procter, 2006; Mortera-Gutierrez, 2006; Rausch & Crawford, 2012). Building this sense of community, which is often lacking in online courses (Mortera-Gutierrez, 2006), has the potential to influence student perceptions of learning (Rausch & Crawford, 2012). It is also important to maintain that sense of connection throughout the course, such as through student collaborations (Ackerman, 2008; Beck & Ferdig, 2008) and continuing the discussion outside of the classroom (Osguthorpe & Graham, 2003). Online discussion boards can be a great way to establish a sense of community (Cole & Kritzer, 2009). For example, Heinze and Procter (2006) implemented a "Virtual Café" where students could meet and have informal discussions. This could be used as an area devoted completely to students so they do not feel hindered in their discussions. However, a disclaimer might be implemented regarding faculty involvement to the extent that discussions do not violate any school policies. Other designated discussion boards could be used in a similar way. For example faculty could create a "Getting to Know You" discussion board to foster introductions between students and faculty (Cole & Kritzer, 2009). Additionally, Cole and Kritzer (2009) used brief weekly video messages to help build a sense of presence and community. Although not a discussion board, the videos served a comparable role.

Students should also be made aware at the beginning of the course what is expected of them and what they can expect from the course (Strayer, 2012). For example, Lage and colleagues (2000) described to students the time and effort it would take to be successful in the flipped course and encouraged students to transfer to a different course section if they did not believe they would succeed with such a format. To help students with time management, faculty should include suggested timelines for viewing online lectures and materials so that students stay on track and are prepared to participate online and in class (Foertsch et al., 2002). One way to meet students' organizational needs is to create modules based on course themes (Cole & Kritzer, 2009). In addition, students might find it helpful if faculty explain the reasoning, or elaborate on learning objectives, course structure, or particular assignments (Groves & O'Donoghue, 2009). This might be especially useful in blended courses where there is not as much structure to in class routines as traditional courses (Strayer, 2012).

Assignments and learning objectives: To help reduce confusion and endless student emails, faculty should be as explicit in describing student assignments as possible (Mortera-Gutierrez, 2006). This includes how and where assignments should be turned in. Faculty who suggest the use of email to submit every assignment are often inundated with student emails (Mortera-Gutierrez, 2006). Beck and Ferdig (2008) also suggest switching from traditional assignments to more online projects.

It is also important that learning objectives align with the blended format, meaning adjustments will likely be needed for faculty transitioning to a blended format (Mortera-Gutierrez, 2006; Tao et al., 2011). For example, faculty may have to work to transition from content-focused to learner focused (Beck & Ferdig, 2008; Kim & Bonk, 2006). McDaniel and Caverly (2010) suggest focusing first on specifying the learning objectives to help guide in class and online materials. Furthermore, course objectives should be centered on student learning versus content; otherwise the online portion of the course could become a simple communication tool instead of a learning tool (Mortera-Gutierrez, 2006). Similarly, learning assessments will need to be modified to align with the new learning objectives (Kim & Bonk, 2006; Zapatero et al., 2012).

Faculty involvement: It is important for faculty to be involved in course elements, whether they are inside or outside the classroom. One way to stay involved outside of the class is to hold online office hours for students who might need help outside of class or has to work during regular office hours (Cole & Kritzer, 2009). In addition, faculty involvement in online discussion boards signals to students the importance of those course elements. However, it is important for faculty to determine the optimum amount of participation; too much involvement online may hinder participation and too little may reflect a lack of interest to students (Cole & Kritzer, 2009). Faculty can also increase student learning and continuity by ensuring in class activities are related to online discussions (Stacey & Gerbic, 2007). Although how to best be involved may require training, many faculty want and expect it to improve blended learning (Beck & Ferdig, 2008; Kim & Bonk, 2006).

Face-to-face and online elements: Tao and colleagues (2011) note that in blended teaching, more research has been devoted to studying the online methods of teaching than the face-to-face methods. They examined four different blended courses, with a focus on best practices during face-to-face classes. First, to motivate students to view the prerecorded lectures and read assigned texts, the authors suggest starting face-to-face classes with a short quiz. Students reported such methods helped them prepare for the face-to-face classes. If lectures are given during face-to-face classes, the focus should be on enhancing the prerecorded lectures as well as addressing material students found challenging. Tao and colleagues also encourage the use of laptops in the classroom by faculty and students, which has shown to increase student directed learning. Faculty can also employ the laptops for electronic testing, which the majority of students in this study preferred. Clickers, or classroom response devices, can also be used in the classroom as a metacognitive tool. Students use these devices to answer questions and get immediate feedback that allows them to assess their learning as well as helps faculty gauge student learning. Games and group work can also be integrated into course work to help with learning and engagement.

Students also report a number of steps faculty can take to improve learning through the use of online lectures. For example, students recommend faculty devise the online lectures so that students are able to interact with the material by pausing and rewinding, see the amount of needed to view the lectures, view the lectures without the internet in case there is a problem with connectivity (e.g., place lectures on a CD) (Foertsch et al., 2002). Additional student recommendations include the avoidance of simple webcam headshots (Schullery et al., 2011).

Course structure: Many faculty are also experimenting with inverting the classroom or using a flipped course structure. Basically, work that is traditionally completed in class is done outside of class and vice versa (Lage et al., 2000). For example, Cole and Kritzer (2009) used voiced-over slide presentations, readings, and online activities (e.g., discussion boards) that students completed outside of class. Face-to-face time was used to briefly review the materials students covered at home and work on applying the material in small groups. Students reported learning more in the face-to-face sessions in comparison to traditional lectures where students passively learn. McDaniel and Caverly (2010) flipped their developmental math course and propose how to best go about creating the class. First, they suggest adapting course objectives to specifically guide the creation of in-class and online materials. Second, they focused on in-class materials including activities and group work. Lastly, they created the prerecorded lectures. Their goal of these lectures was to introduce students to course concepts so they could build a foundation of knowledge to pull from during class activities.

Many faculty are adopting this structure in order to focus more on projects, problem-solving, and real-world applications and less on lectures and passive learning (Cole & Kritzer, 2009; Foertsch et al., 2002). However, Foertsch and colleagues note that even with a student-centered approach, lectures are still needed to convey foundational knowledge from which students can apply in projects, and group work. They argue that the content of lectures is not the problem, but when they are delivered to students. Students are most likely to have questions when they are working on problems versus when they are listening to a lecture. Therefore, one could argue that lectures should be viewed outside of class, much like reading a text, and class time should be devoted to students working on assignments where faculty are able to observe where students are struggling (Cole & Kritzer, 2009; Foertsch et al., 2002).

Employing such practices, Lage and colleagues (2000) flipped a microeconomics class. Students viewed prerecorded lectures on their own time and class time was devoted to covering the materials more in-depth. Students were also provided with PowerPoint slides for each unit that they could use for taking notes, raising questions in class, and as a reference. The beginning of each face-to-face class started with student questions that often lead to mini-lectures followed by hands-on labs and experiments, as well as worksheets and application questions that students completed individually and then reviewed in groups. To ensure attendance, worksheets and application questions were randomly collected. The instructors also created a course homepage to offer students more support with PowerPoint slides, assignments, optional interactive quizzes, a discussion board geared toward applying the material, and a chat room where instructors held online office hours. Overall student perceptions of the course were positive, with the majority of students reporting a preference for the flipped format in future courses and that they learned more with the flipped format and group work. It is also interesting to note that most students felt they put in about the same amount of time and work as they have in their traditional courses. The instructors' perspectives were also positive. They felt students were more motivated, possibly due to greater student responsibility for learning with the flipped format. They also believed student collaboration aided in learning, with students often referring to in class activities and experiments on tests. From their own perspective, faculty viewed the flipped course as more enjoyable to teach due to greater student involvement, unpredictable class discussions, and more one-on-one time with students.

Feeling like face-to-face time was not effectively being utilized, Foertsch and colleagues (2002) flipped their once lecture-based computer science course so that lectures and reading materials were viewed outside of class and face-to-face time was devoted to group work and problem-solving. Faculty and teaching assistants noted an increased workload, but the payoff was the face-to-face classes were more enjoyable to teach. In addition, the course format allowed faculty to better observe and facilitate student learning and intervene when help was needed. Overall, the majority of students also provided positive feedback on the course format. Student believed the flipped structure better allowed them to work at their own pace and to view lectures when they felt they were most receptive to learning. Most students reported watching the lectures, especially to prepare for face-to-face classes, and believed the prerecorded lectures were more helpful for taking notes because they could go back and replay sections as needed. However, some students did not like the flipped structure because they felt they could not ask questions as they arose when watching the lectures, struggled to pay attention to online lectures, and were less likely to take notes because online notes were provided.

Others have implemented the flipped course pedagogy to address many of the issues that arise with increasing student enrollment (Foertsch et al., 2002; Schullery et al., 2011). For example, Schullery and colleagues (2011) flipped their course structure because less and less faculty were willing to teach classes with hundreds of students, there were concerns that students were truly learning through passive lectures and multiple-choice exams, as well as a means to increase student engagement. The flipped course structure allowed for more student interaction through the faculty transitioning from lecturers to facilitators of learning. Students also reported feeling more connected to faculty as a result of this change. The course structure also provided opportunities for deeper learning by using the lectures to build foundational knowledge of course topics, which can be applied during face-to-face meetings. In addition, the authors note a flipped classroom better meets the needs of students with short attention spans who are looking for immediate gratification, incorporation of technology, and to be involved in their learning.

Keeping the advantages, barriers, and best practices in mind we developed a flipped classroom pedagogy to teach psychology statistics. In the upcoming section, the course is fully described. In addition, we assessed student outcomes, including understanding of statics content, cultural sensitivity, and student attitudes toward statistics. The results of the study are discussed as well as more general application of flipped classroom methodology and overall conclusions.

FLIPPED PSYCHOLOGY STATISTICS COURSE: A FIELD EXPERIMENT

A unique and nontraditional course was developed and administered to undergraduate students at a large, public, liberal arts university. The course was for Psychology Statistics and its structure followed a blended learning model that essentially flipped traditional homework with in-class work. The new course structure was designed to achieve a learner-centered environment, where the focus was on the student rather than the material being taught. Students viewed lectures online at home rather than passively learning in class. The lectures were video recordings of the two instructors that were then uploaded to a university webpage dedicated to the course. A lecture was generated for each of the major sections of the chapters in the textbook. PowerPoint slides were also created that accompanied each lecture. Students printed the slides and were encouraged to make note of questions or points of confusion to be discussed with the professor during face-to-face time. Viewing lectures at home created time in-class to work on problem sets that would normally be completed as homework assignments. They consisted of 15 multiple-choice questions, five open-ended questions, and 10 true or false questions. Answers to the questions were provided to students in the study guide. This allowed for immediate feedback to students on their performance, but also offered the opportunity for students to cheat. To circumvent this temptation and to foster deep processing of conceptual statistics understanding, students were required to elaborate on why the chosen answer was correct. Problem sets were turned in each week and students were required to show all work including an explanation of the correct answer for each problem.

A second unique aspect of the new structure was the focus placed on diversity inclusion into the curriculum. "Application days" were scheduled throughout the course where students applied the statistical principles they learned to real world situations related to social justice issues. For example, a guest faculty member presented research related to gender equity. On another application day, a graduate student presented research related to race discrimination. Students read articles written by the guest speaker's prior coming to class. Class time was then devoted to understanding the researcher's social issue and analysis of some of the speaker's data. Furthermore, a final course project required students to analyze quantitative information students collected regarding a social justice topic of their choice in which there was a "pro" side and a "con" side. The projects were shared with the class during a poster presentation session that modeled that of psychology professional conferences. In addition, students were individually responsible for writing a short American Psychological Association (APA) style manuscript describing their study, analyses, and results.

Method

Participants

Participants included undergraduate students at a liberal arts state university in the Northeast enrolled in Psychology Statistics courses (i.e., two flipped courses and two traditional courses). See Table 1 for participant demographics.

Materials and Procedure

Students completed a series of surveys at the beginning of the semester and again at the end of the semester. The first instrument was the Survey of Attitudes towards Statistics Scale (SATS; Schau,

Table 1. Participant demographics

	Hybrid (n **= 50)**	**Traditional** (n **= 59)**

Other	4	1.7

Stevens, Dauphinee, & DelVecchio 1995, Schau, 1999). The SATS assesses four components of attitudes toward statistics. These include affect (e.g., positive and negative feelings about statistics); cognitive competence (e.g., students' intellectual knowledge and skills when applied to statistics); value (e.g., usefulness, relevance, and worth of statistics in personal and professional life); difficulty (e.g., difficulty of statistics as a domain). Items are answered on a 7-point Likert scale. In this study, pre and posttest Cronbach alphas for each subscale were .85 and .91 for affect, .89 and .89 for cognitive competence, .85 and .87 for value, and .82 and .79 for difficulty.

The second instrument the students completed was the Cultural Sensitivity Scale (Chen & Starosta, 2000). This scale consists of 24 items that measure six affective elements of intercultural sensitivity, including self-esteem, self-monitoring, open-mindedness, empathy, interaction involvement, and suspending judgment. An overall score is computed from this assessment with a higher score indicating higher levels of sensitivity in intercultural interactions (Chen & Starosta, 2000). Pre and posttest Cronbach alphas for the current study were found to be .97 and .72.

The third measure was an assessment of statistical content knowledge. This assessment consisted of 14 multiple-choice items that were developed by a faculty member who was considered an expert in psychology research and statistics. The faculty member was blind to the hypothesis of the study, thus creating an objective assessment strictly on the material in the textbook. In addition, all of the instructors were prohibited from seeing the assessment until after the study was complete. The assessment was scored for number of correct answers and was given to students at the beginning and end of the semester.

Differences between Course Structures on Outcome Measures

To understand how course structure, pretest scores (i.e., statistics knowledge, ISS, and SATS), and posttest scores (i.e., statistics knowledge, ISS, and SATS) the following analyses were performed. First, ANOVAs were performed to determine whether there were group differences on any of the pretest and posttest scores. Although there were no significant differences on pretest scores between groups, there were differences in the mean scores suggesting possible confounds (see Table 2). Specifically, the students in the flipped course scored slightly higher than the students in the traditional course on a number of the measures. Looking at just posttest scores, those in the flipped course scored significantly

higher on statistical knowledge ($F(1, 107) = 7.092$, $p = .009$, $\eta_p^2 = .062$) and the Intercultural Sensitivity Scale ($F(1, 107) = 6.026$, $p = .016$, $\eta_p^2 = .062$) at the end of the semester. All other differences were not significant. Next, a MANCOVA was performed to examine whether controlling for the initial slight confounds between course structure and pretest scores changes the posttest scores across the course structures. After controlling for pretest scores, statistical knowledge at the end of the semester was still higher in the flipped course ($F(1, 101) = 4.256$, $p = .042$, $\eta_p^2 = .040$), however scores on the ISS were no longer significantly different ($F(1, 101) = 3.238$, $p = .075$) and no other significant differences were revealed.

Exploratory Results

Exploratory analyses were also performed to examine whether demographic differences exist. No significant differences were found for gender. Looking at year in school, significant differences were found for a number of pretest scores using ANOVAs and post hoc Tukey tests (see Table 3). Generally, first year students were significantly higher on intercultural sensitivity ($F(3, 105) = 15.547$, $p < .001$, $\eta_p^2 = .314$), SATS: affect ($F(3, 105) = 4.228$, $p = .007$, $\eta_p^2 = .112$), SATS: cognitive competence ($F(3, 105) = 2.908$, $p = .038$, $\eta_p^2 = .076$), and SATS: difficulty ($F(3, 105) = 4.007$, $p = .010$, $\eta_p^2 = .103$). Similar analyses were performed to examine group differences on posttests revealing significant differences for SATS: cognitive competence ($F(3, 105) = 2.796$, $p = .044$, $\eta_p^2 = .075$) and trends for SATS: affect ($F(3, 105) = 2.527$, $p = .061$, $\eta_p^2 = .066$) and SATS: difficulty ($F(3, 105) = 2.261$, $p = .086$, $\eta_p^2 = .070$), with third year students scoring significantly higher than second year students on affect and cognitive competence and fourth year students tending to score higher than others on difficulty.

DISCUSSION

Results from the psychology statistics course study suggest the flipped classroom structure significantly improved learning, but no differences were found between groups regarding attitudes toward statistics. Similarly, the flipped course showed a greater increase in intercultural sensitivity over the course of the semester, but after controlling for pretest scores was no longer significant. There were no significant differences between courses in regards to changes in attitudes toward statistics. However, this is not surprising. Previous studies have found small, if any, differences between pre and posttest scores (Schau, 1999). Schau suggests these findings may be due to students' overconfidence in their abilities to perform statistics at the beginning of the semester and/or their misunderstandings of what statistics can do for them. Interesting demographic differences were found regarding year in school that supports this claim.

At the beginning of the semester, it appears that first year students held the majority of positive attitudes. First year students held significantly more positive attitudes toward statistics than fourth year students. First and third year students also believed they had more cognitive competence, or statistical knowledge and skills, than fourth year students. In addition, first and second year students thought statistics were less difficult than fourth year students. However, by the end of the semester, the differences by years decreased so that only third year students had more positive attitudes toward statistics and believed more in their statistical knowledge than second year students. Looking at overall trends, it appears as though first year students began the semester feeling confident and positive about statistics in comparison to fourth year students. However, this appears to flip by the end of the semester. Examining mean changes by year, first and second year students' attitudes toward statistics become negative over the course of the semester, whereas third and fourth year students' attitudes became more positive. It could be that first year students who feel confident about their statistical knowledge are more likely to take the course early in their college career, versus those who put off taking statistics possibly due to their lack in confidence. In addition, over the course of the semester, those who overestimated their skills and knowledge come to find that statistics is harder than they thought, whereas those who lacked faith came to find how they had more skills and knowledge than they thought.

It is also important to discuss the additional learning opportunities the flipped course structure offered over the traditional course, without sacrificing course content (Lage et al., 2000). Common themes of these opportunities revolve around flexibility and students taking control of their learning. For example, as long as students maintained a minimum course grade, face-to-face workshop classes were optional. Brothen and Wambach (2007) also allowed students to do certain assignments online (vs. in class) as long as they maintained an acceptable grade. However, a number of students still chose to do work in class even though they had permission. We found similar results, with many students of varying talent still attending the workshops to complete their assignments. Some students likely needed the structure whereas others might have preferred having the instructor readily available in the event they needed assistance. It was also a time where students could work together and receive additional support, which are opportunities students reportedly appreciate (Groves & O'Donoghue, 2009; Strayer, 2012). We also created an informal online discussion area meant only for students for those who did not attend workshops and/or those working after class. Similarly, Heinze and Procter (2006) implemented a "Virtual Café" where students could have informal discussions online in an attempt to foster a sense of community.

The flipped structure also allows for greater flexibility in what is covered and how. For example, having the lectures online allowed for other face-to-face meetings to be used to apply statistics to diversity related research topics through readings, demonstrations, and guest speakers. Senn (2008) recommends using class time for hands on demonstrations or for examples in which students need to be shown step-by-step. Furthermore, these additional learning opportunities better prepared students to complete their own diversity related research project, which they picked as long as they met the course criteria. Giving students this control has been found to increase the variety of topics covered, examples used, and class discussions (Dengler, 2008). Similar to our experiences, Stacey and Gerbic (2007) found that students recognized the benefits of blending online and face-to-face formatting and employed the course elements that best addressed their needs. Specifically, students who were grouped together for a course project scheduled times to meet in person as well as shared important project documents online. This same collaboration has not been found in comparison to traditionally formatted classes (Strayer, 2012).

Application to Other Courses and Fields

The psychology statistics course described above is an example of a flipped classroom that utilizes blended learning though Internet technology. We suggest that any college level course could be flipped in a very similar way. Lectures can be assigned as homework, streamed online or as downloadable files. As was done in the statistics class, professors could video-record staged lectures created especially for the course. Another option is to record live-lectures that took place within real classes during a previous semester. These real, but recorded lectures, could then be posted online, or for students who have limited access to the Internet, the professor could provide the needed files to the students on a compact disk or a jump drive (Foertsch et al., 2002). Other options for lectures exist such as podcasts (audio recording only) or PowerPoint slides with voice over. Such lectures can be made on a PC using the Acrobat Pro program or on a Macintosh using the iMovie application (Lage et al., 2000).

To better understand how the flipped classroom might look in various academic domains, consider the following examples. In a science class, such as biology, chemistry or anatomy, students could view PowerPoint files with voice over prior to coming to class. Class time could then be used in a more traditional science lab situation. Students would have twice as much time to work on experiments or worksheets as they would in a traditional course. Or, consider a course taught in an art or design department. Students could view pre-recorded lectures of professors demonstrating artistic, skillful, and difficult techniques. Students would be able to study and re-watch the videos so that when they come into the classroom they are able to immediately practice the new skill. Time spent working on the projects would be increased. In this case, the professors are truly modeling skills for their students, who can learn through the observation and in-class practice.

In the above examples students are able to spend class time conducting experiments, working in groups, or individually on their own projects. Self-directed study could also be used during class time (Lage et al., 2000). If one chooses to spend class time in this way, we would suggest that interactions between the faculty and student should still be cultivated and remain a focus of the time spent together. Foertsch and colleagues (2002) argue that being able to ask questions, and receive timely answers is a key feature of a flipped classroom. Students often do not know they have questions until they are actively working on the material. This is when they first become aware that they have a misunderstanding. When work is being done in class (instead of at home), students will be able to generate questions and interact with the professor to get the answers they need. Asking questions and receiving immediate feedback should lead to a better understanding of the course material (Foertsch et al., 2002).

Class time can be spent in additional ways then those already described. For example, reading prior to coming to class is an important aspect of many college courses. Professors struggle to get their students to consistently read. The flipped classroom could help in this problem. In-class time could be used to quiz students or give them other low-stakes assessments. Use of such quizzing is thought to increases students reading at home. Studies have also found that repetitive quizzing of course material increases retention of that material later on, a phenomenon referred to as the testing effect (McDaniel, Anderson, Derbish, & Morrisette, 2007). If quizzing is not a desired method, professors could have students generate questions for review that the class spends time covering together.

Although most of the examples of flipped classes in the literature have been small we encourage professors to extend such pedagogy to courses with a larger numbers of students. Lage and colleagues (2000) suggest that their flipped economics course could be done with large class size, but that professors might break students up into smaller recitation sections. If recitation sections are not possible, professors could employ teaching assistants and implement random collection and grading of work. For example, if a course runs 16 weeks, and students work in class to complete weekly-assigned worksheets (problem based learning), a total of six assignments could be collected and graded. The collection times would be random and unannounced during the semester.

CONCLUSION

Foertsch and colleagues (2002) asked what could face-to-face classes be used for if they were not used for lecturing? They note lectures are most effective when used as another source of information, much like a textbook. In this sense, lectures can be viewed outside of class and “face-to-face class time may then be used for more pedagogically powerful interactive exercises" (p. 273). Similarly Cole and Kritzer (2009) note the flipped classroom provides, "a more efficient use of instructional time" (p. 38). Students work on gaining foundational knowledge on their own time so that class time can be used for deeper learning through application of the material they learned. Similarly, many students mark the success of a learning environment through opportunities in the course to apply what they have learned (Strayer, 2012). The research presented in this chapter suggests there are a number of additional learning opportunities that a flipped course structure offers over the traditional format. In the current study, both courses had the same homework assignments, tests, and textbook but the flipped course allowed for additional readings to apply the material, application days, and a final project.

However, it is important to note that the flipped course structure might not fit every course, instructor, or student (Beck & Ferdig, 2008; Osguthorpe & Graham, 2003; Strayer, 2012). As mentioned previously, faculty need to determine which blend of best practices is best suited to meeting the learning needs of students (Groves & O'Donoghue, 2009; Heinze & Procter, 2006). However, faculty might be hesitant to transition to a blended format for a number of reasons. Foertsch and colleagues (2002) note the increased time commitment and challenges to flipping a course, but believe teaching such a course is more fun because it allows faculty to better interact with students and facilitate learning. Flipped courses may be front loaded in terms of preparation, but this allows for more time throughout the rest of the semester to prep for in-class activities, tweaking the course, as well as decreases the amount of time needed for future courses (Cole & Kritzer, 2009). Faculty might also be concerned about whether students will view lectures if put online. However, the majority of students report watching most of the lectures, especially to prepare for face-to-face classes (Foertsch et al., 2002).

These are great examples demonstrating the importance of establishing course and student expectations at the beginning of the course so students can make an educated decision regarding whether they want to stay enrolled in the course. Addressing such concerns ahead of time will help make for a pleasurable learning experience for students, and decrease negative course evaluations (Foertsch et al., 2002).

KEY TERMS AND DEFINITIONS

Blended Learning Theory (BLT): BLT is a pedagogical approach to instruction that is a combination of face-to-face, computer mediated activities, and online learning that is rooted in Active Learning Theory.

Blended Teaching: Integration of classroom face-to-face learning with online learning.

Cognitive Taxonomy Theory (CTT): A modified version of Bloom's original Cognitive Taxonomy. CTT categorizes and identifies six cognitive domains including remembering, understanding, applying, analyzing, evaluating, and creating.

Distance Learning: Courses that are taught away from an institutions physical campus including online and hybrid formats.

Flipped Classroom: Consists of a restructuring of traditional face-to-face classroom learning. Flipped classrooms employ blended learning by using the Internet to deliver content to the students, frequently assigning lectures to be viewed online while students are away from school.

Hybrid Classroom: Combines online and face-to-face delivery where by any amount of content is delivered online, while the rest is delivered in a reduced number of face-to-face class meetings.

Problem Based Learning Theory (PBLT): A student-centered pedagogy that focuses on a project or problem that is experienced by the students as means for instruction.

This work was previously published in Promoting Active Learning through the Flipped Classroom Model edited by Jared Keengwe, Grace Onchwari, and James N. Oigara, pages 23-46, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

Chapter 8
Blended Learning and Technological Development in Teaching and Learning

Kennedy E. Umunadi
Delta State University, Nigeria

Nwachukwu Prince Ololube
University of Education, Nigeria

ABSTRACT

This chapter examines blended learning and technological development in teaching and learning. This study is based around the suggestion that technological development can emerge in Nigeria when an enabling environment and other necessary facilities for blended learning are made available in different institutions for teaching and learning. This chapter addresses the following topics: net generation and use of technology outside of schools, the digital environment, computer use and blended learning in schools, well-constructed digital environments, teaching and blended learning, the shift from teaching to learning, student-centered methods, theories supporting the new view of the learning process, play way method, group instructional methods, Vygotsky's socio-cultural theory, Skinner's theory of learning, Jean Piaget, Jerome Bruner, problem-based learning, anchored instruction, distributed cognition, cognition flexibility theory, cognitive apprenticeship, situated learning, self-regulated learning, and entry behaviour/residual knowledge.

INTRODUCTION

Blended technology-aided learning, as distinct from learning about technology, has the capacity to transform learning environments in ways that are still difficult for most educators to imagine (Ololube, 2011). Although children in today's schools have only known the digital world, many adults continue to experience great difficulty using basic computer functions such as email, search engines, and presentation software (Ololube, 2009). For the first time in human history, the young are thus more confident with and fluent in the dominant technologies of the day, than the adults charged to teach them.

DOI: 10.4018/978-1-4666-8246-7.ch008

Blended learning is regarded as a new concept in developing countries like Nigeria, although it is a concept that will greatly facilitate programme development in technology. Ausburn (2002) argues that the demand for mass customization of Technology-Based Learning (TBL) will require a shift from traditional models of instructional design and development to the new blended learning which brings together the traditional model and the ICTs that can lead to technological development in teaching and learning. This blended learning is in fact central to new and emerging paradigms of education. In this paper, blended learning is defined as the combination of different learning strategies to reposition learners for an optimal future in a technological society.

We live in a high-speed, wired world, where digital technology is interwoven into the fabric of our lives and our society. It is part of out homes, our businesses and our schools. Tapscott (1999) asserts that we need to look to youth in relation to how best to use technology in education. He refers to youth as the Net Generation or N-Geners – the first generation to grow up surrounded by digital media and to assume that it is part of the natural landscape of life (p.7).

Prensky (2001) refers to young people today as Digital Natives for they are "all native speakers" of the digital language of computers, video games and the Internet (p. 1). Those who entered and adopted this networked, digital world, in other words those who were not born into it, are deemed Digital Immigrants (Pensky, 2001). Ololube et al. (2012) and Prensky (2001) notes that there are important, never-before seen differences between Digital Natives and Digital Immigrants and that the new abilities, skills and preferences of the former are to a large extent misunderstood or ignored by the current generation of educators. These educators are, at the same time, being challenged to think differently about teaching and learning with technology.

Preparing teachers for 21st century blended learning requires a close look at what it means to teach and learn in increasing networked, technology-rich, digital classrooms, e-libraries, and auto-CAD rooms (Ololube & Egbezor, 2009). Teacher preparation programs need to create intentional learning environments where pre-service teachers can explore relevant issues and develop pedagogies that are effective for an era of blended learning. These teachers need an opportunity to develop new images and expertise to design and facilitate meaningful technology-aided blended learning (Ololube, 2011).

NET GENERATION AND USE OF TECHNOLOGY OUTSIDE OF SCHOOLS

Growing up with digital media and the Internet has resulted in the Net generation's ubiquitous use of new technologies. Youth do not necessarily approach digital media and network technologies as add-ons in their worlds, but rather as integral components of their world. Thus, according to Tapscott (1999), youth use the Internet to manage their personal finances, organize protest movements, check facts, discuss issues, check the scores of their favourite team and chat online with its superstars, organize groups, cast votes, learn more about illnesses, attend a virtual birthday party, or get video clips from a soon-to-be-released movie (p.7).

In a study by The Future of Children (2000), 72 children ages 5 to 18 were surveyed from Plugged In and The Computer Clubhouse in late 1999 and early 2000. These children reported participating in a variety of computer-based activities associated with blended learning including traditional educational projects such as writing and researching school projects and seeking homework assistance online. Their hobbies included e-mail, online chats, programming and Web-page development and they noted that drawing pictures, surfing the Web, writing letters and game playing were some of their favourite computer activities.

THE DIGITAL ENVIRONMENT

A most promising finding from Watson (2008) and Ololube and Egbezor (2009) concerns the effectiveness of well-designed digital and online environments in engaging pre-service teachers in the range of issues that surround teaching and learning with technology. Whether these environments provided the primary structure for courses, as in the case of social studies and virtual field trips, or provided a collaborative and mentored planning environment, the findings were remarkably consistent: well constructed digital environments can enhance face-to-face teaching and learning. It is clear that continued attention to the design of such environments and increasing use of them to create media rich, interactive environments for learning holds great promise in terms of addressing many contemporary education problems. Watson (2008) also revealed that students valued computers in their lives for entertainment, as a tool for accomplishing the goals of blended learning, and as a vehicle leading to present and future competence, autonomy, and empowerment.

Audio books offer another example of the creative use of digital technology with youth. The Calgary Herald recently reported that teenagers are accessing audio book Websites and digital books using MP3 technology (Harris, 2004). Thus we know that in addition to reading books, youth are listening to them. The richness of the multimodality provided by digital media, however, extends both more deeply and more broadly, in the lives of children and youth today.

Clifford (2004) suggests that digital experiences that are a regular part of students' lives outside of school represent fundamentally different ways of thinking and interacting with others. First, hypertext, graphics and sound have created knowledge structures that are three dimensional. Every student who surfs the net knows about this, even if they cannot articulate it in these academic terms. Second, students are far less interested in receiving information that others think they should have, and far more interested in creating personalized spaces where they can download what they want, when they want it, how they want it. They want to be immersed in environments in which they can direct perspectives, request others to provide information they need, and surround themselves with interesting sound and pictures. They want to make things happen in these environments. As part of a postmodern culture, they expect to be able to re-use and re-purpose digital objects at will. Third, their literate world includes time as a crucial dimension. News is reported to the tenth of a second and they like to jump quickly between and among sequences; they multi-task. Fourth, they are increasingly creating a public, not just an audience, for their work. They contribute to fan fiction sites that invite others around the world to view episodes of favourite film and television shows through different lenses. They critique dominant power structures in phenomena called "Culture Jamming" or "Sniggling." They chat with one another in real time and maintain complex asynchronous relationships in gaming and other digital environments. They wear computers, and they carry their handheld devices and cell phones everywhere.

COMPUTER USE AND BLENDED LEARNING IN SCHOOLS

Given financial investment in ICT in schools and students immersion in technology outside of school, how are they using ICT in schools? It has been argued that a disconnect exists between youth use of technology in their personal lives and use of technology in schools. Technology tends to be marginalized and used in instrumental ways only within the conventional educational framework. Becker (2000), looking at the 1998 Teaching Learning and Computing (TLC) U.S.A National Survey, reports that word processing was the most common application used in schools and that analytic or product-oriented software was used less often.

Corbett and Williams (2002) reported that in 2000, approximately one third of students used computers to assist them in learning school materials, while only a quarter used them for programming, drawing, painting, graphics, or analyzing data with spreadsheets (p. 15). Plante and Beattie (2004) concur and note that the three most frequently integrated technology applications in Canadian teaching practices according to school principals are word processing, using the Internet/intranet to distribute information, and using software for blended learning for the special needs of students and/or remedial programs. The least frequently used applications were "software supporting creative works" and "spreadsheets and database software for simple data manipulation and statistical analysis" (Plante & Beattic, 2004, p. 23).

WELL-CONSTRUCTED DIGITAL ENVIRONMENTS PROVIDE ENGAGING AND MEANINGFUL INTERACTION FOR STUDENTS

A number of particular post-secondary innovations point to the power of well-designed online and digital learning environment to enhance teaching and learning processes. These innovations and their advantages are explored next with students and faculty from the University of Lethbridge, the University of Calgary and the University of Alberta.

At the University of Lethbridge Online, students enrolled in introductory courses reported experiencing their online environment as so engaging and their relationship with their instructor so meaningful that they felt little need for the face-to-face sessions that had been built into the program to facilitate the development of such relationships. Student teachers noted that rather than having lectures and too many class discussions that are dry, they were in the lab on computers answering interesting questions, seeing videos from the classroom, and hearing other education students talk about their experience. For these students, their online experiences were almost as valuable as student teaching because they were able to observe students interacting and hear other student teachers. Students at the University of Alberta likewise spoke especially highly of their work with video clips involving classroom teachers, categorizing these clips as opportunities to find out what real teachers think and do.

When participants cite such a range of experiences as deeply engaging and satisfying, we must pay attention to the design of those learning experiences and what they have in common. First, these experiences created an opportunity for students to engage in sustained digital environments in which they were, in one way or another, relating issues of technology integration directly to issues of teaching and learning perceived as immediately relevant and meaningful. They learned about technology integration and explored a range of applications within a context of purposeful use that had something of the character of a "just-in-time" in-service. This replaces the "just-in-case" structure of conventional technology courses and workshops of which students were generally quite critical.

Second, each of the courses involved some kind of mentorship by faculty and sometimes by others. The emphasis on meta-teaching at the University of Lethbridge made students feel that their instructor was deeply involved in the particular issues, questions and problems that were important to them. They developed relationships with their instructor, and with one another, through the work they were doing individually and collectively.

At the University of Calgary, face-to-face mentorship by both the instructor and professional development mentors was readily available to students on a "pull" basis as they and their co-operating teachers collaborated in constructing and teaching technology-rich inquiries. Here, the social studies virtual tour immersed students in genuine problems of practice in social studies teaching, and the combination of resources available through the tour – carefully structured assignments and complementary course work – created for students, an experience they characterized as real and as deeply engaging. Both their instructor and the lab assistant were easily accessible for support consultation and problem solving.

Third, each of the environments was carefully structured and deliberately open-ended. None had the flavor of older versions of computer assisted learning in which participants move through static content and are tested for mastery. Rather, each was in some sense an immersive environment in which students made significant choices about the kinds of interactions they would structure for themselves.

Faculty reported that it was not easy to turn dissatisfaction with conventional methods of teacher preparation into new (online) environments where conventional best practice skills tend to replicate course delivery as a defining metaphor. Changing this thinking was identified as one of the significant challenges each university encountered, and characterized both the scholarly and the pragmatic nature of work that faculty must do in order to create new learning environments for their students. We were struck by how each environment, in very different ways, was designed to force students to encounter key problems of practice in a problem solving mode.

Fourth, each enabled students to move at their own pace, to engage more or less deeply in the environment or to "pull" what they needed, how they needed it. Both proficient and inexperienced technology users described this advantage, sometimes explaining that the course was designed to let you go as deeply as you needed, or to quickly get past required applications and ideas that were already familiar so as to try new and more difficult things. It was also acknowledged that if students wanted to meet the basic standards set by the course, they could do that and direct greater attention to other courses or areas in which they did not feel so strong.

In a similar vein, University of Calgary students and field supervisors reported that the addition of the online planning and communications environment enhanced communication between students and their field supervisor, between practicing teachers and students, between practicing teachers, students and professional development mentors, and among students themselves. In this case, the work of experienced teachers to understand effective ICT integration in inquiry-based classrooms was openly acknowledged as a professional development initiative that paralleled those of pre-service teachers. Here, educators working together addressed the fact that teachers must learn to make more deeply informed observations and decisions about curriculum design, classroom instruction, and ICT integration, not just superficial judgements about student and teacher behaviour or digital add-on's that fail to meet the spirit of the C Level of the Program of Studies. In all three cases, digital environments of a particular character seemed well suited to help pre-service teachers learn to make the necessary informed decisions, observations and integrations.

Many faculty also turn to products such as WebCT and Blackboard to bring course content online. Their use of these platforms is however, what Norton and Wiberg (1998) call "second generation" technology use – doing familiar things in digital ways. A study on successful faculty development for the use of WebCt at Purdue University (Hua Bai, Chuvessiriporn, Lehman, 2002) confirms this picture of the ways in which the online environment is often used for teaching and learning. Most (59%) used WebCT for basic content presentation such as putting course notes, syllabi and assignments online. Many (41%) posted and organized student's grades and used the quizzes and survey features. WebCT email (71%) and discussion forums (82%) were among the most popular features. Few faculty members had experimented with the WebCT live chat feature.

TEACHING AND BLENDED LEARNING

Teaching is both a science and an art. As noted, the emphasis of teacher education is to improve the quality and effectiveness of teaching which in turn influences the quality of learners. No educational system can rise above the quality of its teachers (FRN, 2004). Teaching consists of the teacher behaviour or activities designed and performed to produce a change in student (learners) behaviour. In a formal sense, it is the organized work adults do in the school system in the form of conscious efforts to help the learners in their care to acquire desirable knowledge, skills, habits and values in an atmosphere of mutual freedom, trust and respect.

Teaching is a service profession and the teacher guides and directs learning activities for the development of the learner. He does this by motivating and arousing the learners' desire to learn, helping them to establish goals and giving them the stimulus and opportunity to ask questions so as to obtain information and propose possible solutions to problems. Through teaching, the learner is led to practice technological skills, draw inferences, acquire valuable habits/attitudes, analyze results and achieve other desirable outcomes (Opute–Imala, 1997).

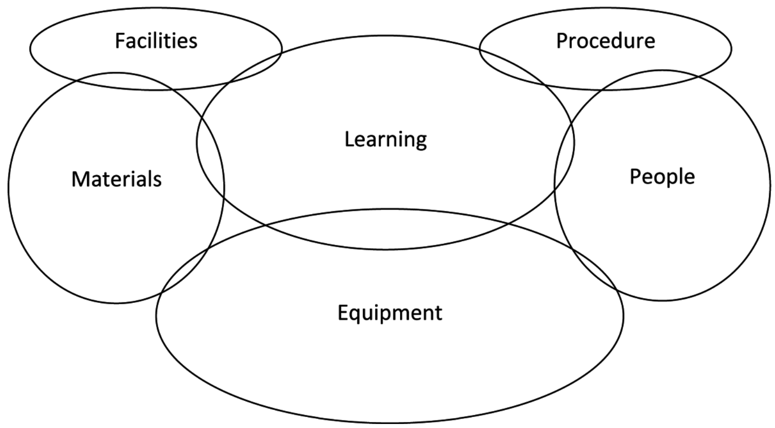
Teaching is a complex art of guiding learners through a variety of selected experiences geared towards the balanced development of the individual. In teaching today the emphasis is on the learner hence the notion of "child-centered education" in curriculum literature. It is also a science in that it involves the possession of technological skills as a specialized body of knowledge. Since the schools cannot be stronger than their teachers (as the operator/key agents in the implementation of the curriculum and those responsible for blending different types of teaching methods in the classroom), the teacher can be viewed as the hub of the educational system. The effectiveness of any system depends on the quality and devotion of the individuals involved in teaching, blending different skills and methods towards the development of learners.

Teaching, according to Nweke (1990), is an occupation based on specialized intellectual study and training, the purpose of which is to supply skilled service and advice to others for a definite fee or salary. Teaching is an essential social service that helps to socialize the individual. Since education through teaching prepares individuals for various occupational roles, teaching then is a profession par excellence – the key to all other professions, for through it, others come to realize their aspirations.

Blended learning can be realized through the blending of old and current methods with emerging technology for the actualization of the educational objectives. In practice, blended learning is often education that combines face-to-face classroom methods with computer-mediated activities. According to its proponents, this strategy creates a more integrated approach for both instructors and students. The goal of blended learning is to provide an efficient and effective instruction experience by combining delivery modalities. In teaching, the term blended learning describes a solution that combines several different methods, such as collaboration software, Web-based courses, EPSS, and knowledge management practices. Blended learning also is used to describe learning that mixes various event-based activities, including face-to-face classrooms, live e-learning, and self-paced instruction.

To design blended training, instructional designers start by analyzing the training or course objectives and breaking them down into the smallest possible pedagogically (for children) or andragogically (for adults) appropriate segments (learning object). After the course or training has been segmented, the best approach for delivering each segment (learning object) is identified. In some cases the best approach might be online learning but in others it might be live instruction. The course is then aggregated by grouping the

Figure 1. Learning systems simplified (source: Davies, et al., 1974)



instruction logically while taking into account the medium of delivery. In this way, one may require a few lessons online and some others live (Olugbenga, 2012).

LEARNING

Learning in pursuit of knowledge can modify the behaviour of the learner. There is a general consensus that learning means modification of behaviour as a function of practice. Thus, it takes place when the performance of the organism is changed through stimulating contacts with the environment. Learning accounts for differences in behaviour which are not due to factors such as maturation, sensory adaptation or other phenomena which may produce observable changes in the activities of the organism. Learning may be motor muscular (or kinesthetic), cognitive/mental/intellectual and effective (attitudinal) or a combination of these (Blended Learning). All basic elements of curriculum are designed around the learner and interact to achieve balanced and full development of the learner (See Figure 1).

Learning is an on-going process of thinking, acting, doing and responding to different situations. To lead to a happy and full life, individuals must acquire habits or ways of behaving through adaptation to their environment (learning). Learning is the relationship between stimulus (s) (independent variable) and response (dependent variable) and thus determines how new stimulus-response connections are formed. It requires meaningful stimulus to elicit meaningful response and is a process of perceptual organization and re-organization, structuring and re-structuring and the re-organization of the cognitive field of the learner. It is imaginative, creative and purposive enterprise and includes conceptualization of concepts and shifting of responses to new stimuli. It is pervasive and because of its pervasiveness, people see it in different ways as determined by the environment.

Learning is process that is complimentary to other processes like motivation and perception. In line with the prior, it is a relatively permanent desirable change in behaviour or conduct as a result of past experience or training. Learning can manifest as a change in performance which is an index of learning through general activity, practice and experience. This change is more or less permanent in nature.

In order to fully understand the concept of learning, a series of basic questions can be posed. These include who, what why, when, where and how of human learning?

Table 1. Teacher-centered learning and learner-centered learning environments

	Teacher-Centered Learning Environment	Learner-Centered Learning Environment
Classroom activity	Teacher-centered didactic	Learner-centered interactive
Constructional emphasis	Facts, memorization	Relationships, inquiry and invention
Concept of knowledge	Accumulation of facts quantity	Transformation of facts
Demonstration of success	Norm referenced	Quality of understanding
Assessment	Multi-choice items	Common referenced portfolio and performance
Technology use	Drills and practice	Communication, access, collaboration, expression

- **WHO:** The learner and his characteristics
- **WHAT:** Content and subject matter to be learnt
- **WHY:** Readiness (tasks given should be proportional to learners readiness)
- **WHERE:** Learner environment (natural or physical, political and social)
- **HOW:** Learning process/method

Psychologists have identified eight types of learning. These are signal, stimulus-response, chaining, verbal association, discrimination, concept learning, rules, and problem solving. Some of the factors or conditions that influence learning are:

- **Learner Factor:** Personality (age, gender, interest, readiness, social relationships, home environment, general disposition etc.).
- **Internal Factor:** Closely linked with the prior, this includes intellectual/mental achievement level or ability and heredity.
- **External Factor:** Environment (rural/urban, in/outside classroom, instructional resources, teacher's perceptions, etc.). Poor environments result in low quality learning and anxiety, fear, stress, and anger inhibit learning. The absence of these in addition to conducive environments, emotional stability, and social drives promote learning.

A SHIFT FROM TEACHING TO LEARNING

As technology has created change in all aspects of society, so it has changed our expectations of what students must learn in order to function in the new global economy. Students today must learn to navigate large amounts of information, to analyze and make decisions, and to master new increasingly technological knowledge domains. It is important that students grow into lifelong learners, collaborating with others to accomplish complex tasks and effectively using different systems for representing and communicating knowledge to others. A shift from teacher-centered instruction to learner-centered instruction has thus been required to enable students to amass 21st century knowledge and skills.

Table 1 (Sandholtz, Ringstaff, and Dwyer, 1977) articulates the dynamics involved in the shift from a focus on teaching to a focus on learning. Shifting from teaching to learning can create a more interactive and flexible learning environment for teachers and learners. This new environment also involves a change in the roles of both teachers and students. As shown in Table 2 (adapted from Newby et al., 2000), the role of the teacher changes from that of knowledge transmitter to that of learning facilitator, knowledge guide, knowledge navigator and co-learner. This new role does not diminish the importance

Table 2. Changes in student and teacher roles in learning-centered environments

	Teacher Role	
	A shift from:	**A shift to:**
1.	Knowledge transmitter, primary source of information, content expert and source of answers	Learning facilitator, collaborator, coach, mentor, knowledge navigator and co-learner
2.	Teacher controls and directs all aspects of learning	Teacher gives students more options and responsibilities for their own learning
	Student Role	
	A shift from:	**A shift to:**
1.	Passive recipient of information	Active participant in the learning process
2.	Reproducing knowledge	Producing and sharing knowledge, participating at times as expert
3.	Learning as a solitary activity	Learning collaboratively with others

Source: Adopted from one developed by Newby et al. (2000)

of the teacher but requires new knowledge and skills, particularly in technological development. Students assume greater responsibility for their own learning in this environment as they seek out, find, synthesize, and share their knowledge with others. ICTs provide powerful tools to support the shift to student-centered learning and the new roles of both teacher and learner.

Student-Centered Learning

Student-centered learning includes several teaching methods such as discovery, play-way, and group instruction.

Discovery Method

This method, as the name implies, is a method through which the pupils discover things for themselves. Pupils are put in the position of pioneers and find their way along the path of knowledge as did those who first discovered the facts, principles and laws which are now known to all.

Play-Way Method

This method often involves a game played to enable pupils to carry out real life situations. It is a pleasurable activity with a definite purpose. The play-way method can involve games, drawing, dramatization, modeling with clay, etc.

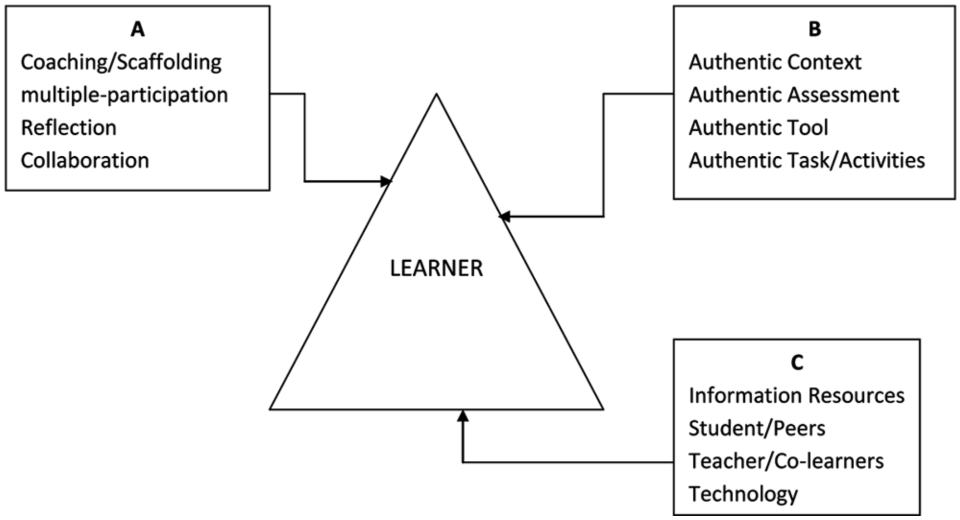
Group Instructional Methods

Group instructional methods include methods like storytelling, lectures, demonstrations, discussions and folklore.

THEORIES SUPPORTING NEW VIEWS OF THE LEARNING PROCESS

New perspectives on the learning process and the shift to student-centered learning have emerged based on cognitive learning research and the confluence of several theories that have informed our understanding of the nature and content of learning. Some of the most prominent theories include socio-cultural theory (based on Vygotsky's intersubjective and zone of proximal development), constructivism theory, self-regulated learning, situated cognition, cognitive apprenticeship, problem-based learning (cognitive and technology group at Vanderbilt), cognitive flexibility theory (Spiro et al, 1988) and distributed cognition

Figure 2. Modified triangular student-centered learning environment



(Salomon et al., 1993). Each of these theories is based on the same underlying assumptions that learners are active agents, purposefully seeking and constructing knowledge within a meaningful context. The learning environment that may be derived from this view of learning is show in Figure 2.

The student-centered environment illustrated in Figure 2 shows that learners interact with other learners, teachers, information resources, and technology. The learner engages in authentic tasks, in authentic contexts using authentic tools and is assessed through authentic performance. The environment provides the learner with coaching and scaffolding in the development of his or her knowledge and skills. It provides a rich collaborative environment enabling the learner to consider diverse and multiple perspectives for addressing issues and solving problems. It provides learners with blended opinions of ideas that can lead to new concepts. This is the thrust of this work. The environment also provides opportunities for students to reflect on their learning. It is important to note that this new learning environment can be created easily through the use of old technology. At the same time, it is clear that ICTs are powerful tools for helping learners to access vast knowledge resources, collaborating with others, consulting with experts, sharing knowledge and solving complex problems using cognitive tools. ICTs also provide learners with powerful new tools to represent their knowledge through text, images, graphics and video.

Theories of Learning

Learning is the process by which we acquire and retain attitudes, knowledge, skills and capabilities that cannot be attributed to inherited behaviour patterns or physical growth. Capacity for learning is related to innate physiological factors, while rate of learning depends on both inherited and environmental factors (Farrant, 1981). Each type of learning goes by a different name:

1. Affective learning has to do with feelings and values and therefore influences attitudes and personalities.
2. Cognitive learning is achieved through mental processes such as reasoning, remembering and recall. It aids in problem solving, developing new ideas, and evaluation.
3. Psychomotor learning has to do with the development of skills which require effi-

cient coordination between our brains and muscles, as when we read or write or carry out physical skills such as balancing, skipping or jugging.

There are two main ways of learning:

1. **Deductive Learning:** This describes the process by which a learner is presented with a hypothesis or general principle and applies a number of tests to it to discover whether or not it is true.
2. **Inductive Learning:** This describes the reverse process of deductive learning. In it, the learner examines related matters to see whether any general conclusion can be drawn.

A number of theories have been put forward to explain how we learn. All of them have conceived of learning as a process that progresses in stages. John Fedrick Herbert, a German philosopher and educator who worked in the early part of the nine tenth century, saw learning as a progression through five stages.

1. **Preparation:** Setting the scene for new knowledge by drawing together previous knowledge that is relevant.
2. **Presentation:** Introducing the selected new knowledge to the learner.
3. **Association:** Relating the new knowledge to existing knowledge.
4. **Systematization:** Making sense of the new knowledge in readiness for its use.
5. **Application:** Using new knowledge.

Constructivist Views of Learning

The new view of the learning process is based on research that has emerged from theoretical frameworks related to human learning. Many reflect a constructivist view of learning. In this view, learners are active agents who engage in their own knowledge construction by integrating new information into their schema or mental structures. The learning process is seen as a process of "meaning-making" in socially, culturally, historically and politically situated contexts. In a constructivist learning environment, students construct their own knowledge by testing ideas and approaches based on their prior knowledge and experience, applying these ideas and approaches to new tasks, context and situations, and blending or integrating the new knowledge gained with pre-existing intellectual constructs.

A constructivist environment involves developing communities comprised of students, teachers and experts who are engaged in authentic tasks in authentic contexts closely related to work done in the real world. A constructivist learning environment also provides opportunities for learners to experience multiple perspectives. Through discussion or debate, learners are able to see issues and problems from different points of view so as to negotiate meaning and develop shared understanding with others. The constructivist learning environment also emphasizes authentic assessment of learning rather than the traditional paper/pencil test. Some of the most influential theories that relate to new constructivist views of the learning process include:

Vygotsky's Socio-Cultural Theory

Vygotsky's socio-cultural theory of human learning describes learning as a social process and as the origination of human intelligence in society or culture. The major theme of Vygotsky's theoretical framework is that social interaction plays a fundamental role in the development of the cognitive. Vygotsky believed that everything was learnt on two levels: first through interaction with others, and then integrated into the individual mental structure. Vygotsky also contended that the potential for cognitive development is limited to a "Zone of Potential Development" (ZDPD). This zone is the area of exploration for which the student is cognitively prepared, but requires help and social interaction to fully develop (Briner, 1999). A teacher or more experienced peer provides the learner with "scaffolding" to support the learner's evolving understanding of knowledge domains or his or her development of complex skills. Collaborative learning, discourse, modeling and scaffolding are thus seen to support the intellectual knowledge and skills of learners and facilitate intentional learning.

Given Vygotsky's theory, learners should be provided with socially rich environments in which to explore knowledge domains with their fellow students, teachers and outside experts. ICTs can support this type of learning environment by providing tools for discourse, discussions, collaborative writing, and problem-solving, and by providing online support systems to scaffold students evolving understanding and cognitive growth and development.

Skinner's Theory of Learning

Skinner, a contemporary American psychologist looked upon learning as a series of experiences each of which influences behaviour in the same way that conditioning does. Thus, in his view, each learning experience is a stimulus that produces a behavioural response. Those who see learning in this way belong to the behaviourist school of psychology. It is this learning theory that has given rise to programmed learning as a system of instruction (Farrant, 1981).

Jean Piaget

Jean Piaget based his research on the development of children's cognitive functions. His work is regarded by many as the founding principles of constructivist theory. He observed that learning occurs through adaptation to interactions with the environment. Disequilibrium (mental conflict which demands resolution) gives rise to the assimilation of a new experience (which is added to the existing knowledge of the learner) or to accommodation (modification of existing understanding to allow for the new experience).

Jerome Bruner

Bruner, similar to Piaget, believed that learning is an active process in which learners construct new ideas or concepts based on their prior knowledge and experience. He identified three principles to guide the development of instruction: (1) instruction must be concerned with the experiences and context that make the student willing and able to learn (readiness); (2) instruction must be structured so that the student can easily grasp the material (spiral organization); and (3) instruction should be designed to facilitate extrapolation and/or fill in the gaps (going beyond the information given).

Problem-Based Learning (PBL)

Problem-based learning is intended to help students in different fields to develop higher order thinking skills by providing them with authentic and complex problems and cases. This approach to learning provides a more authentic context for learning and engages students in authentic tasks. Through this process of working together, using blended ideas, articulating theories and critical ideas, creating hypotheses, discussing the ideas of others, students move to deeper levels of understanding of the problem.

Anchored Instruction

Anchored instruction is a real world approach to solving problem. It is designed instruction anchored in a real world context, problem or real situation. This can be done, for example, through the use of video to create "real world context" for subsequent learning and instruction (Bransford & Stein, 1993).

Distributed Cognition

Distributed cognition emphasizes that cognitive growth happens through interaction with others and involves dialogue and discourse, making private knowledge public, and developing new understandings. In support of distributed cognition, tools for online collaboration have been designed to support collaborative knowledge construction and sharing in the classroom (Oshima, Bereiter, & Scardamalia, 1995).

Cognition Flexibility Theory

Cognition flexibility theory asserts that people acquire knowledge in ill-structured domains by constructing multiple representations and linkages among knowledge units. It also notes that learners revisit the same concepts and principles in a variety of contexts. Cognition flexibility theory is useful in understanding how knowledge is transferred in ill-structured knowledge domains (Spiro et al., 1988).

Cognitive Apprenticeship

Cognitive apprenticeship refers to the instructional process in which the teacher or more experienced or knowledgeable peers provide "scaffolds" to support learners' cognitive growth and development. Cognitive apprenticeship permits students to learn through their interactions, construct knowledge and share knowledge-building experiences with other members of the learning community. ICTs provide powerful new tools to support cognitive apprenticeships, enabling groups to share online workspaces to collaboratively develop artifacts and intellectual products. These tools also make possible tale-apprenticeships, in which an expert or mentor is able to work with a student who may be thousands of miles away.

Situated Learning

Situated learning occurs when students work on authentic tasks that take place in real-world settings (Winn, 1993). It emphasizes the use of apprenticeship, coaching, collaboration, real world contexts, tasks, activities and cognitive tools (Brown, Collins and Duguid, 1989). Situated learning provides an authentic context for the learner and encourages social interaction and collaboration in the learning environment. Through this kind of collaborative problem solving, dialogue and discussion students are able to develop deeper levels of understanding of a problem or knowledge domain.

Self-Regulated Learning

Self-regulated learners are those who are aware of their own knowledge and have an understanding of what they know and what they do not know or still need to know. It combines self-observation and self-reaction. Self-regulation plays a crucial role in all phases of learning and has the potential to increase the meaningfulness of students' classroom learning (Schoenfeld, 1987). ICT tools can be used to make students' tacit knowledge public and to help them to develop meta-cognitive skills and become more reflective and self-regulated learners (Hsiao, 1999).

Entry Behaviour/ Residual Knowledge

Entry behaviour/residual knowledge is a concept proposed in this paper to represent the entry behaviour of graduates at both the secondary and primary school level in terms of ICT use. This basic knowledge that students carry with them from one educational level to the next will assist them in improving their learning abilities relative to those who are not literate and/or skilled in computer use. Entry behaviour/residual knowledge supports the situated learning theory in which a learner can work on an authentic task with basic knowledge acquired from the conventional method of teaching.

Teaching Circuits/Electronics

Matos (2001) developed workbenches and instructional and learning software for teaching electronics to educators. Today students and electronics teachers rely on electronic workbenches and printed circuit board layout software for circuit analysis, design, and simulation. His is the only electronics' design automation for designing electricity and electronic circuits that includes features specifically for education and teaching. Software use has become the standard in education and teaching at the university, college and high school level. It is highly effective in education, economical, easily integrated into a curriculum, mimics today's digital environments, and most importantly, is easy to use. Students tend to learn faster and retain course content longer when they use circuits and electronics workbench software. Teachers teaching electricity and electronics prepare circuits, changing values as needed and so can demonstrate the changing electrical behaviour of a circuit in a digital environment.

Cedra and Sabonnadiere (2002) constructed Cedrat-circuits for teaching and learning circuits in schools. Cedrat-circuits are geared toward instruction in computation and the design of static converters for power electronics (pulse generators, converters, rectifiers, inverters and equivalent circuits of electric motors). The versatility of Cedrat-circuits makes them well suited to teaching and learning electricity and electronics.

Using Cedrat-circuits increases the number of circuits one can study and allows for more detailed examination of each circuit. Cedrat-circuit analysis is much faster than repeated construction and examination of prototypes. By allowing the rapid modification of the circuit, adding or deleting components or changing their values, one can gain a greater understanding of the operation of the circuit. Consequently, Cedrat-circuits are of great interest to colleges.

With the Cedrat-circuit, the user can focus on the design of the device by selecting its components and positioning them on a grid. Once the schematic design is finished, the designer can then define the characteristics of each component, such as values, control frequencies, phase shifts, and switching times. During this characterization, the user may employ parameters and vary them between different simulations. Computation of the solution is completely automatic.

Attia (1995) developed Mat lab for teaching electronics. Mat lab is numeric computation software for electricity and electronics calculation. It is being used to teach circuit theory, filter design, random processes, control systems and communication theory. Mat lab matrix functions are shown to be versatile the analysis of data obtained from electronic experiments.

The purposes of incorporating these packages into the curriculum are twofold: (1) to enhance the theoretical understanding of electricity and electronics principles and concepts; (2) to allow students to solve fairly complex problems that would otherwise be impossible without computer-aided designs and computer-aided technology. Since Mat lab is also a programming environment, users can extend the functional capabilities of Mat lab by writing new modules. Mat lab thus has a large collection of toolboxes for a variety of applications. A tool box consists of functions that can be used to perform computations in the tool box domain, including signal processing, image processing, neutral networks, control systems, statistics, symbolic mathematics, and optimization and system identification.

These theories and tools supporting the new views of learning help to shape new pedagogies for learning. Ultimately, the power of ICTs will be determined by the ability of teachers and learners to use these new tools to create rich and engaging learning environments. According to the UNESCO World Education Report (1998) these new technologies could have radical implications for conventional teaching and learning processes; in reconfiguring how teachers and learners gain access to knowledge and information, these technologies challenge conventional conceptions of teaching and learning materials, methods and approaches. The biggest challenge for ICTs, blended learning and education today, particularly in the developing world is to ensure that the new generation of learners and teachers are well prepared to use these new methods, technologies, processes and materials.

CONCLUSION

In this chapter, a broad spectrum of topics has been examined, although the focus has been on technology and blended learning. Blended learning with technology as distinct from learning about technology has capacity to transform learning environments in ways that are still difficult for many educators to imagine. Prospects for blended learning and technological development in teaching and learning appear slim in Nigeria as we advance into the 21st century. The major fabric of technology education involves training in the process of applying technological skills to practical problems from primary through to the tertiary level of education. As there are no innate barriers to technological development in Nigeria, it will only be able emerge when the enabling environment and its necessary facilities are made available in different institutions of teaching and learning.

KEY TERMS AND DEFINITIONS

Blended Learning: Any form of learning process that combines f2f teaching and learning with computer mediated instruction aimed at knowledge dissemination.

Digital Environment: A promising, effective and well-designed digital and online environments that engage teachers and students in a range of issues that surrounds teaching and learning with technology.

Enabling Environment: A set of interrelated conditions that allows f2f and computer mediated effective learning to take place.

Problem-Based Learning: A process intended to help students in different fields to develop higher order thinking skills that provides them with authentic and complex problems solving methods.

Quality Learning: A central issue in every modern society. A powerful instrument that engages, rewards and enjoyable to our personal and collective experiences.

Quality Teaching: A teaching process that captivate students with subject matter drawn out of themselves, catches their environment like a passing train. A teaching process that do not tie students down, rather pull students along. Teaching that inspire students to compete against themselves and take up tasks that seem to exceed their grasp.

Technological Development: A process that improves the quality of education, social, economic, religion, politics etc. through the diversification of contents and methods that promotes experimentation, innovation, diffusion of information and best practices for the successful development of economies and societies.

Chapter 9
Online Learning in Illinois High Schools:
The Voices of Principals!

Anthony G. Picciano
City University of New York (CUNY), USA

Jeff Seaman
Babson College, USA

Scott L. Day
University of Illinois – Springfield, USA

ABSTRACT

The purpose of this chapter is to examine the role that online learning plays in addressing the thoughts, concerns, and issues facing Illinois high school principals. Data were collected from a sample of high school principals who were members of the Illinois Principals Association with respect to the extent, nature, and reasons for participating in online learning programs. An important aspect of this study was to compare the findings in Illinois to those collected from a national sample of high school principals. It concludes that online learning and blended learning are making inroads into the high schools in Illinois comparably to those in other parts of the country. The results of this study indicate that online and blended learning are becoming integral to a number of high school reform efforts, especially with regard to improving graduation rates, credit recovery, building connections for students to their future college careers, and differentiating instruction.

INTRODUCTION

On April 24, 2011, an article in the *Chicago Tribune* entitled, *Online Learning for Illinois High Schoolers Inspires Praise and Suspicion*, appeared that provided a brief overview of the state of online learning in Illinois high schools. As the title suggests, there were the positives and negatives, the yeas and the nays, that typically arise whenever the use of the latest technology is suggested for changing the way children are educated in this country. Online learning, however, has elicited more than

DOI: 10.4018/978-1-4666-8246-7.ch009

its fair share of proponents and detractors. In the opening paragraphs, this article covered well the state of the debate:

[Online learning] 'can personalize for each student and have incredible rigor,' said Michael Horn of the Innosight Institute…

It's a data-rich environment. You can constantly see what does and doesn't work.

Critics say the trend is more about saving money than improving education, and that the effectiveness of online courses remains unproven.

'We have yet to see a vendor who has made the case that students who lack the motivation to do homework, to engage in class, to manage their time efficiently… will be more successful in online learning,' said Samantha Dolen of Palatine-based District 211 (Keilman, 2011).

This debate is being played out throughout the country as state policymakers and school administrators try to find solutions to improve education especially during severe budgetary times. Newspaper and other media reporters who cover this issue frequently will develop their stories around several individuals (students, teachers, union representatives, principals) who are happy to provide opinions for and against the use of online learning.

The *Chicago Tribune* article goes on to describe that while the state of Illinois introduced a virtual high school initiative in 2001, enrollments and enthusiasm have been modest at best. However, as more and more states move forward with apparently successful virtual schools (i.e., The Florida Virtual School), state and local policymakers are reconsidering this mode of learning. The data nationally are mixed with only a handful of studies (see Picciano & Seaman 2007, 2009, 2010) examining the big picture. Surely, more research is needed at the local school level.

BACKGROUND

The Role of Online Learning in American High School Reform

In the past several years, there has been a growing interest in the role that online learning can play in American high school reform efforts. Education policymakers at the federal, state, and local levels have all began to examine how online learning can improve academic programs, to improve graduation rates, and to provide more options to students. By the same token, these same policymakers have expressed concerns about the viability and efficacy of online learning to make substantial improvements in the American high school. A study by Picciano & Seaman (2010) examining these issues was conducted based on a national survey of high school principals. A summary of the results of this study serves as an appropriate backdrop for the study of online learning in Illinois high schools.

ISSUES, CONTROVERSIES, PROBLEMS

Improving Graduation Rates and Credit Recovery

Improving the graduation rate is perhaps the most important aspect of many high school reform initiatives. The term "credit recovery" refers to courses and other activities that students take to make up courses that they need to graduate. While the need for these courses varies, the primary motive for offering these online courses relates to students having not completed required coursework earlier in their high school careers due to illness, scheduling conflicts, academic failure, and etc. Students needing such courses make up a significant portion of the high school student population that subsequently drops out or are late in graduating. The findings in the Picciano and

Seaman (2010) and Watson and Gemin (2008) indicate that credit recovery has evolved into the most popular type of online course being offered at the secondary level.

A relatively new phenomenon, online credit recovery courses were practically non-existent a few years ago and have now become a dominant form of online course offerings in many high schools. What is particularly interesting is that urban high schools, which historically have the lowest graduation rates of any schools in the country, appear to be embracing online credit recovery as a basic part of their academic offerings (Balfours & Legters, 2004). This finding is corroborated by reports from several providers of online courses that are seeing significant increases in demand for credit recovery courses. Gregg Levin, vice president for sales for Aventa Learning, a for-profit provider of online services to K-12 schools, in a recent article said that demand for online credit recovery courses had increased "eight-fold between 2005 and 2008" (Zehr, 2010). Many high schools have been forced to find solutions to their high school drop-out problems due to pressure from state education departments and federal mandates to improve student outcomes. Online credit recovery appears to be an integral part of the solutions for many of these schools.

Building Bridges to College Careers

An important aspect of the high school reform dialogue has centered on the importance of advising students to stay in school and move onto a college career upon graduation. Students who have set the goals of attending college for themselves are more likely to do well in school and graduate. Rather than waiting for graduation, educators have been developing programs to bridge the high school and college experiences at an earlier time. Whether through advanced placement or registration in college courses as electives, there has been a growing population of high school educators seeking to expand the opportunities for their students to start their college careers while still in high school. While many models for this exist, there have always been logistical issues with regards to transporting students to colleges, training high school teachers to teach college-level courses, articulating courses taken in high school for college credit, and etc. It appears from the Picciano and Seaman (2010) study that online and blended learning courses are increasingly being used to overcome these logistical issues. By enrolling in online and blended learning courses, high school students no longer need to be transported to a college campus, can enroll in college courses taught by college professors, and can be given college credit immediately upon completing and passing their coursework. Data from this study indicate that high school administrators see online elective college-level courses as an effective way for some of the more able students to begin their college careers.

Differentiating Instruction

Christensen, Horn, and Johnson (2008) in a major book on this topic, see online learning as an integral part of high school reform specifically by allowing high schools to customize instruction and to differentiate course offerings to meet a wide variety of student needs. However, while offering a wide breadth of courses is most desirable, doing so in face-to-face mode can be quite expensive. Offering some courses online allow for greater breadth of course offerings without necessarily incurring the same costs. For example, to offer a face-to-face elective course generally requires that there be a certain amount of student interest and enrollment for the course in order to make it cost effective. A student interested in taking elective coursework in chemistry might not be interested in taking an advanced foreign language course and vice versa. To meet the needs of both students, high school schedulers would have to offer both an advanced chemistry and a foreign language course and then hope that there are enough students registered to make them cost-effective. Online and blended courses, on the other hand, can be made available for just a single student and only incur the cost for that one student. The data from the Picciano and Seaman (2010) study consistently indicate that high school administrators see online learning as meeting the diverse needs of their students whether through advanced placement, elective college courses, or credit recovery. Likewise, Watson and Gemin (2008) state "online learning programs are designed to expand high-quality educational opportunities and to meet the needs of diverse students" (p. 3). Indeed, the data indicate that the major reason for offering online and blended courses is to offer courses that otherwise would not be available. This supports strongly the concept promulgated by Christensen, Horn, and Johnson (2008) of the role that online technology can play in differentiating instruction and providing more choices for high school administrators in developing their academic programs.

Financial and Policy Issues

Financial and policy issues continue to be major concerns for high school administrators as they consider online learning. On the one hand, offering online and blended courses makes a good deal of financial sense especially when trying to meet specific needs for small groups of students. This enables schedulers to maximize their full-time faculty resources in required and other popular courses and to minimize offering courses in face-to-face mode for small numbers of students.

On the other hand, administrators, the respondents to the survey, clearly see costs and funding formulae as barriers to expanding and implementing online and blended courses. If administrators decide to develop their own online courses, substantial financial investment needs to be made in hardware and software infrastructure, teacher training and support services. The initial investment for these can be prohibitive. However, if a school contracts out for the majority of its online and blended learning courses, the cost of the provision of local support services might be offset by the savings incurred by having to offer fewer courses in face-to-face mode. With so many providers of online courses, especially those that are non-profit, such as state-supported virtual schools and local colleges and universities, most schools do not find it necessary to develop an in-house online learning program.

The financial issues of more concern may have to do with state and local education policies that follow strict attendance-based funding formulae and do not easily accommodate students taking courses beyond a school district. While most states have developed policies regarding funding formula for online courses, some have not. State virtual schools have proliferated, but the funding formulae for them and the schools that contract with them have not necessarily been optimized. Several reports from agencies and organizations such the Southern Regional Education Board (Thomas, 2008) and the Evergreen Consulting Group (Watson & Gemen, 2009) highlight the fact that policies even in states with well-established virtual schools, need to be reviewed and refined in order to support online learning programs for their K-12 school districts.

The Pedagogy of Online Learning

For a number of years, the pedagogy of online learning has been the subject of concern at every level of education. Educators express concerns and perceptions that online learning is not as effective as face-to-face instruction. Their concerns relate to the students' motivation and maturity levels, study habits and organizational skills, as well as their academic preparedness. These concerns will not likely disappear and exist as a given among many educators. Regardless of the concerns, the decision to embrace online learning has been made and the vast majority of schools are moving forward with their programs and looking to expand them in the future. Picciano and Seaman (2010) suggest that many schools and school districts see benefits to online learning programs that overshadow concerns about pedagogical value. Online learning is seen as a means to broaden and expand student experiences. Beldarrain (2006) also concludes that "new models of teaching can accommodate the needs of the 21st century learner by including activities that allow students to contribute to the learning process at any time, from anywhere" (p. 145). Online learning allows students looking for more advanced work to test and challenge their skills by taking more demanding instructional material. It also allows students who might be at risk to make up coursework that they have missed in order to graduate. These policy decisions are based on the rationale that providing broader access to a secondary education may be of more importance than the concerns and perceptions regarding the pedagogical value of online learning.

Rural Schools in the Vanguard

While online and blended learning are increasingly being seen as an important component of high school reform for all schools, rural schools have been in the vanguard in offering these programs to their students. Researchers (Brown, 2012; De la Varra, Keane, & Irvin, 2010; Picciano & Seaman, 2010), have consistently provided insights into the issues that rural schools have faced and the role that online technology plays in addressing them. These schools have had to overcome significant problems related to funding, teacher certification, and small enrollments that forced them to address creatively the needs of their students. While high schools in all locales (cities, towns, and suburbs) are facing serious challenges, the rural schools probably have the most difficult challenges. With limited tax bases, low enrollments, and difficulty in attracting and keeping certified teachers, their issues are fundamental and can jeopardize their very existence. The data suggest that they are making valiant efforts to overcome these issues and online and blended learning are among the strategies for doing so while providing quality educational programs for their students.

METHODOLOGY

This study of Illinois high schools used descriptive analysis relying extensively on a modified survey instrument designed specifically for our original studies Picciano and Seaman (2007, 2009, 2010). This survey was conducted for the 2010–2011 academic year. For purposes of this study the following definitions were used:

- **Fully Online Course:** A course where most or all of the content is delivered online, and typically has no face-to-face meetings.
- **Blended/Hybrid Course:** A course that blends online and face-to-face delivery, and where a substantial proportion of the content is delivered online, sometimes uses online discussions and typically has few face-to-face meetings.

The "universe of interest" for this study included all public high schools in Illinois. Information on these schools was taken from the Common Core of Data (CCD) from the U.S. Department of Education's National Center for Education Statistics (http://nces.ed.gov/ccd/ccddata.asp).

In the first phase of data collection email survey invitations were sent to 506 high school principals who were members of the Illinois Principal's Association (IPA). Principals who had not responded were sent up to two email reminders. A second stage of data collection was then undertaken sending invitations to all non-IPA member public high schools in Illinois as well as those IPS members that had not yet responded. These invitations allowed the high principal to respond by completing a paper version of the survey and return it in a postage-paid mailer, or by responding online. Both the paper and web-based versions of the survey contained a unique survey identification number.

All potential respondents were informed that the Illinois Principal's Association was sponsoring the survey, that "all participants will have access to a free copy of the survey report, comparing Illinois results to the earlier national studies," and that, "All individual survey responses remain anonymous, only aggregated data are reported." The survey form was composed of two portions, one that applied to all respondents and a second section to be completed only by those schools with online or blended course offerings. The invitation letter and the survey form itself were carefully worded to encourage responses from all school representatives, regardless of their view towards online instruction or whether they were involved with online learning or not.

All data collected were entered into a database, either directly by the respondent if the school responded using the web version or, in the case of paper-based responses, by the researchers. Each entry included the unique survey ID number that was used to link the response to the description data of that school contained in the Education's National Center for Education Statistics Common Core of Data. The data linked from this source included location information (city, town, urban/rural), the grade range for the school, and the number of students enrolled.

All data were investigated for missing or out of range values. All missing data were coded as either structural missing (the question did not apply to the respondent) or as non-response missing (the question did apply, but the respondent did not provide any data). After the survey data were merged with the CCD data, cleaned, and all missing value codes added, they were input into the SPSS statistical package for analysis.

Two-hundred and ten high school administrators participated in this study. This represents 23 percent of all public high schools in Illinois. Sixty-two percent of the principals reported that at least one student in their schools was enrolled in an online course between July 1, 2010, and June 30, 2011. Almost 23% of the responding administrators reported that they had students enrolled in a blended learning course.

RESULTS

Importance for Offering Online or Blended Courses

Figure 1 provides a summary of the responses from the Illinois principals to the question: "Regardless of whether your school is currently offering online or blended/hybrid courses, please indicate how important you believe each of the following items would be to your school in offering or potentially offering online or blended/hybrid courses. Do not consider web-enhanced courses for this question." The options receiving the highest test responses were:

- Permit students who failed a course to take it again - Credit Recovery (74%),
- Provide courses that otherwise were not available (72%),
- Provide additional Advanced Placement courses (60%), and
- Provide for the needs of specific students (58%).

These responses represent the significance of online learning in meeting a variety of student needs whether making up courses that they had previously failed (i.e., credit recovery) or for advanced placement. For the former, the term "credit recovery" has become very popular in recent years and is a fairly new phenomenon in online learning. Meeting needs related to other basic school issues such as extending the school year, finances, pedagogical benefit, and alleviating classroom space were perceived as being of less importance.

Figure 1 provides comparisons of Illinois and national data. In general, the responses in Illinois are comparable to the national data. Additional information on the characteristics of the Illinois sample is available in Table 1.

Figure 1. Importance for offering online or blended/hybrid courses

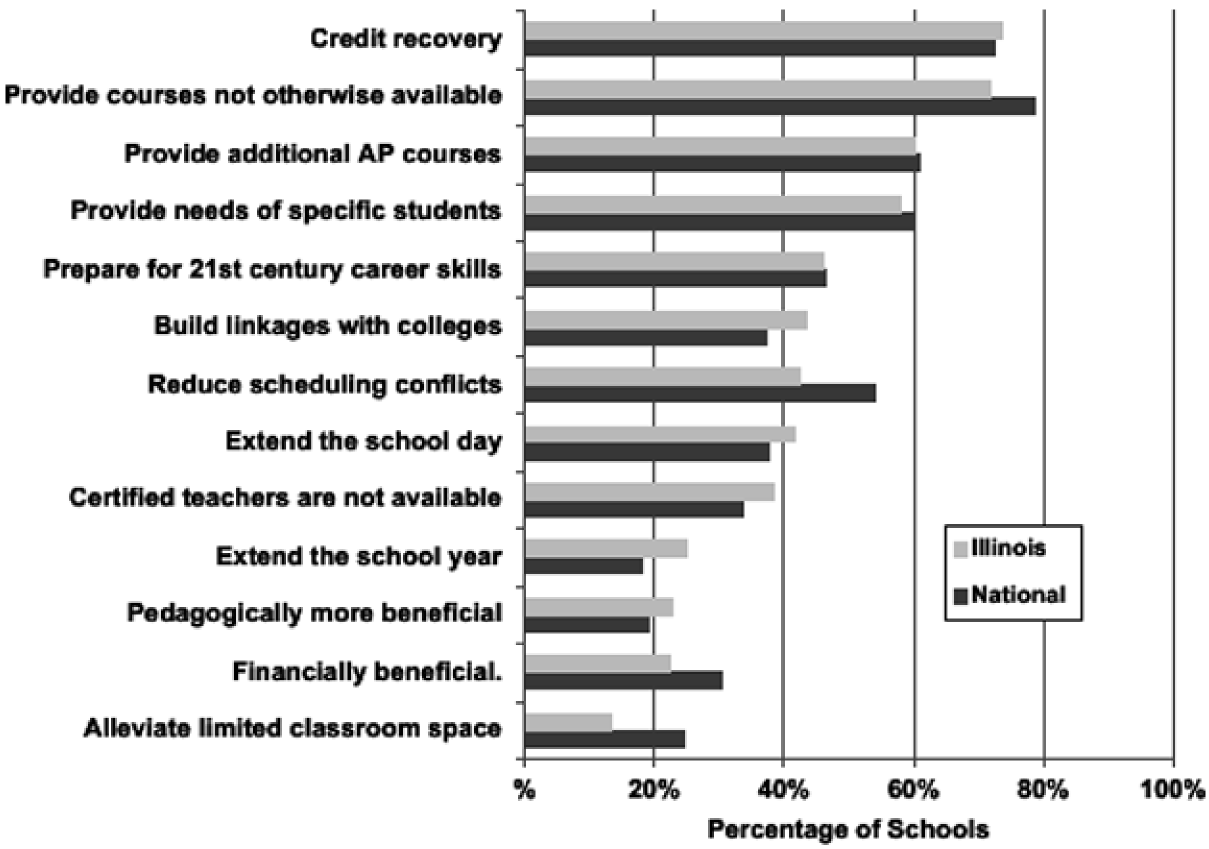

Table 1. Characteristics of Illinois responding high schools

Size Based On		Percent
Student Enrollment	Under 200	28.6
	201 to 500	28.1
	501 to 1200	19.5
	1201 +	23.3
Location	City	8.1
	Suburb	21.1
	Town	27.8
	Rural	43.1

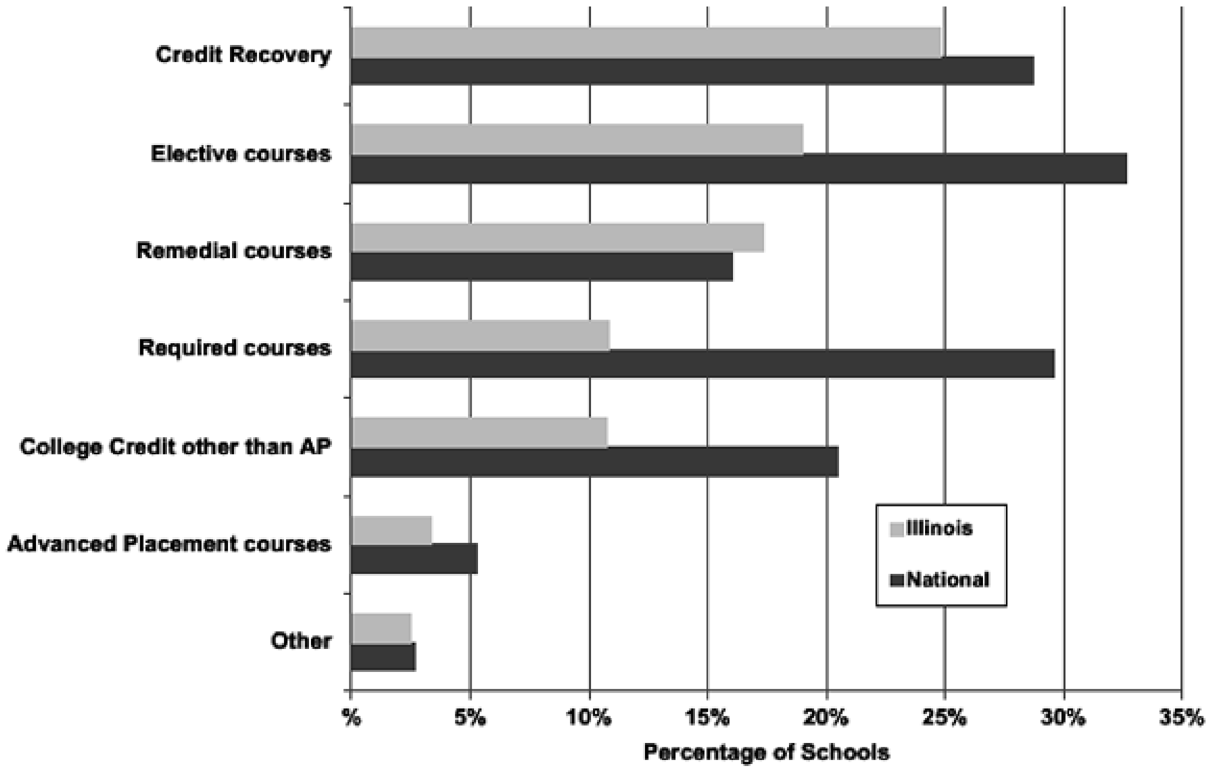
Types of Online and Blended Courses Offered

Figure 2 provide summaries to the question: "What is the nature of online and blended/hybrid courses taken by students in your school (check all that apply)". For both online and blended learning courses, the most popular courses in order of importance were:

- Credit recovery,
- Elective courses, and
- Remedial courses.

Seventy-five percent of the principals reported that fully online courses were being used for credit recovery courses. Results also provide a comparison to the national data. Differences

Figure 2. Types of blended/hybrid courses offered



between the Illinois sample of high schools and the national sample are apparent for elective and required courses.

Providers of Online Courses

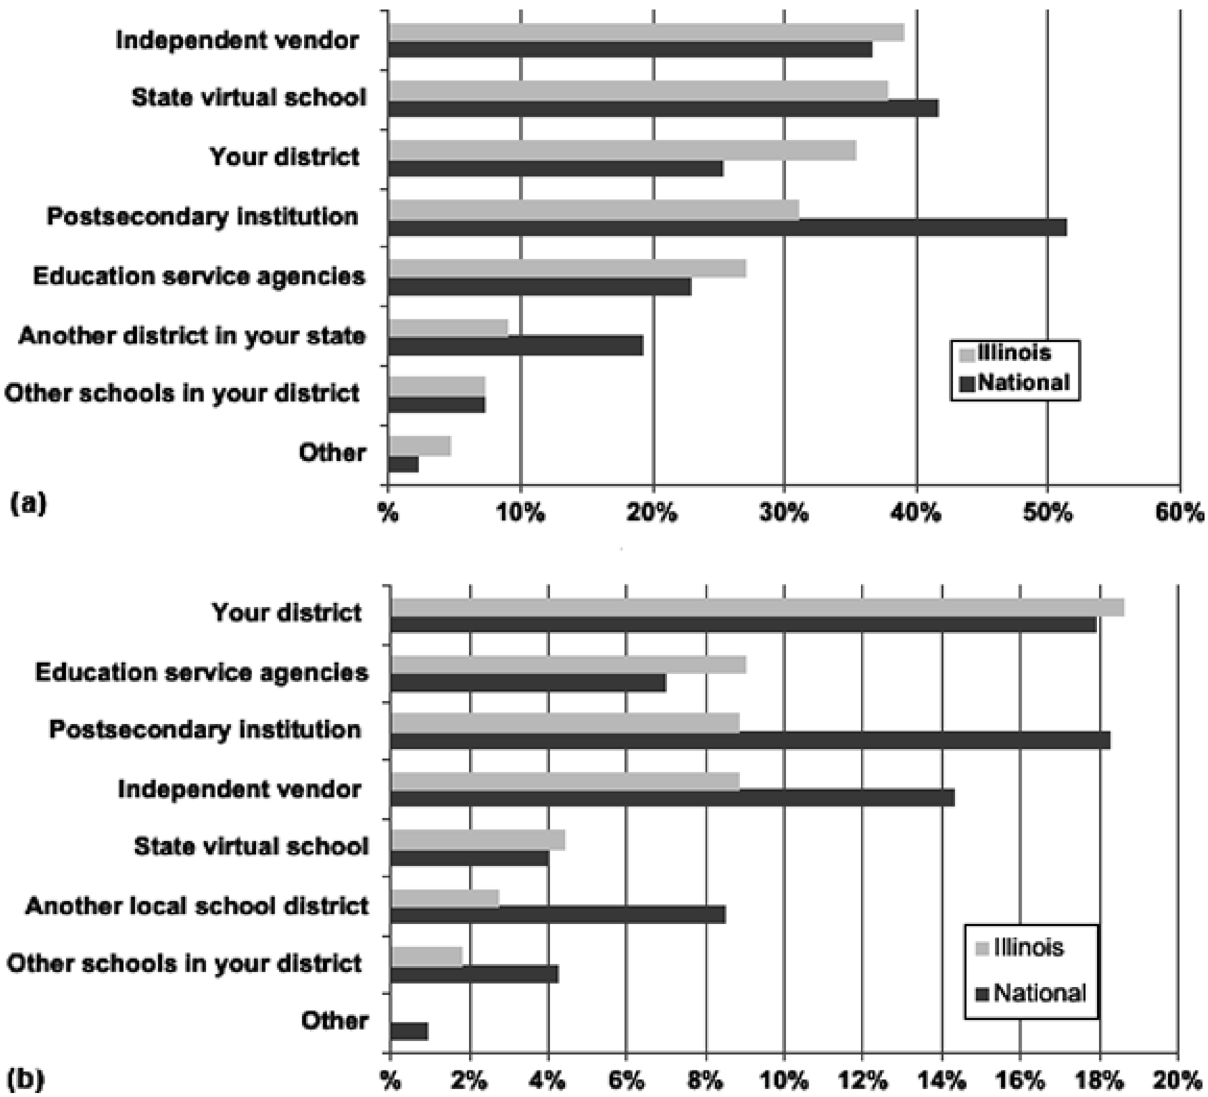
K-12 school districts generally contract out with a number of different providers of online learning programs and courses. Table 2 provides percentage comparisons of samples of Illinois and national high schools in terms of the number of online learning providers being used by the respondents.

Figures 3 (a) and 3 (b) offer summaries of the providers of online and blended learning courses. There are clear differences in the nature of the providers of the two modes of learning. While Illinois high schools use a number of different providers, more fully online courses are provided by independent vendors, state virtual school, and their own school district. Blended learning courses on the other hand, are more often provided by their own school district followed by education service agencies, postsecondary institutions and independent vendors. The rationale for this for blended learning courses is that school districts are tending to utilize in-house teachers and other staff to develop and teach these courses. It also provides a comparison to a national sample of high schools. The most significant difference in these comparisons is the greater reliance on postsecondary institutions at the national level especially for fully online courses.

Table 2. Number of providers of online courses

	National	Illinois
1	35%	47%
2	37%	31%
3	15%	15%
4 or More	14%	7%

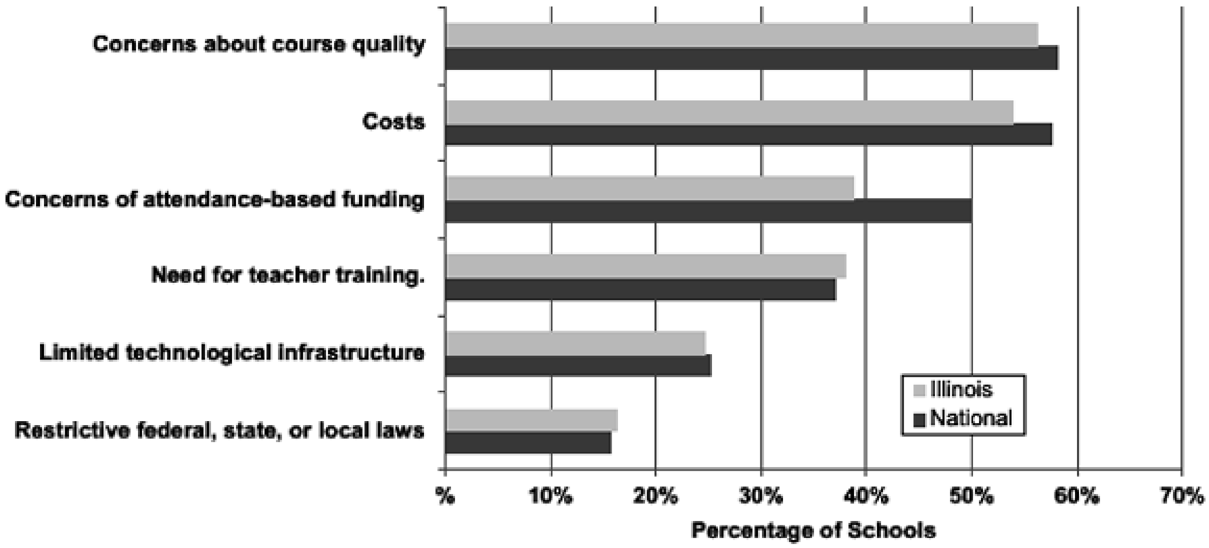
Figure 3. (a) Providers of online courses (b) providers of blended/hybrid courses



Barriers to Online and Blended Learning

Figure 4 provides a summary of the responses to the question: "Regardless of whether or not your school is currently offering online or blended/hybrid courses, how much of a barrier are the following areas to offering or potentially offering fully online or blended/hybrid learning courses? Do not consider web-enhanced courses for this question." Concerns about course quality at 56.2% and cost factors at 53.8% were identified by a majority of the respondents. The need for teacher training and concerns about attendance-based funding also were mentioned by a substantial percentage of principals. The same figure also compares the responses of the Illinois principals to the national sample. The responses are comparable with the exception of "concerns for attendance-based funding" which was considered a more significant barrier among the national sample of principals.

Figure 4. Barriers to offering online and blended learning courses



The Nature of Online and Blended Course Offerings

As part of the planning for this survey, colleagues at the University of Illinois – Springfield asked if the survey could contain several questions regarding the nature of the online and blended learning course offerings specifically related to:

Where (i.e., at home, in school) students take online and blended learning courses?

Type (i.e., led by teacher or adult or self-contained) of online and blended courses?

Interaction (i.e., allow for student interactions or students work independently) within online and blended courses?

Figures 5 (a), 5 (b), and 5(c) provides summaries of the responses to these questions. The responses indicate that students work in several environments at the school (supervised and unsupervised) and at home although the highest response (74.4%) indicated that students work in these courses under the supervision of an adult at the school. Note that any single school could report more than one response for each of these questions – they are "check all that apply." In terms of the type, respondents indicated that 61.1% were self-contained and 46.0% were led by a teacher or tutor. In terms of interaction, the vast majority (86.1%) indicated that students worked independently and did not interact with other students in online and blended courses.

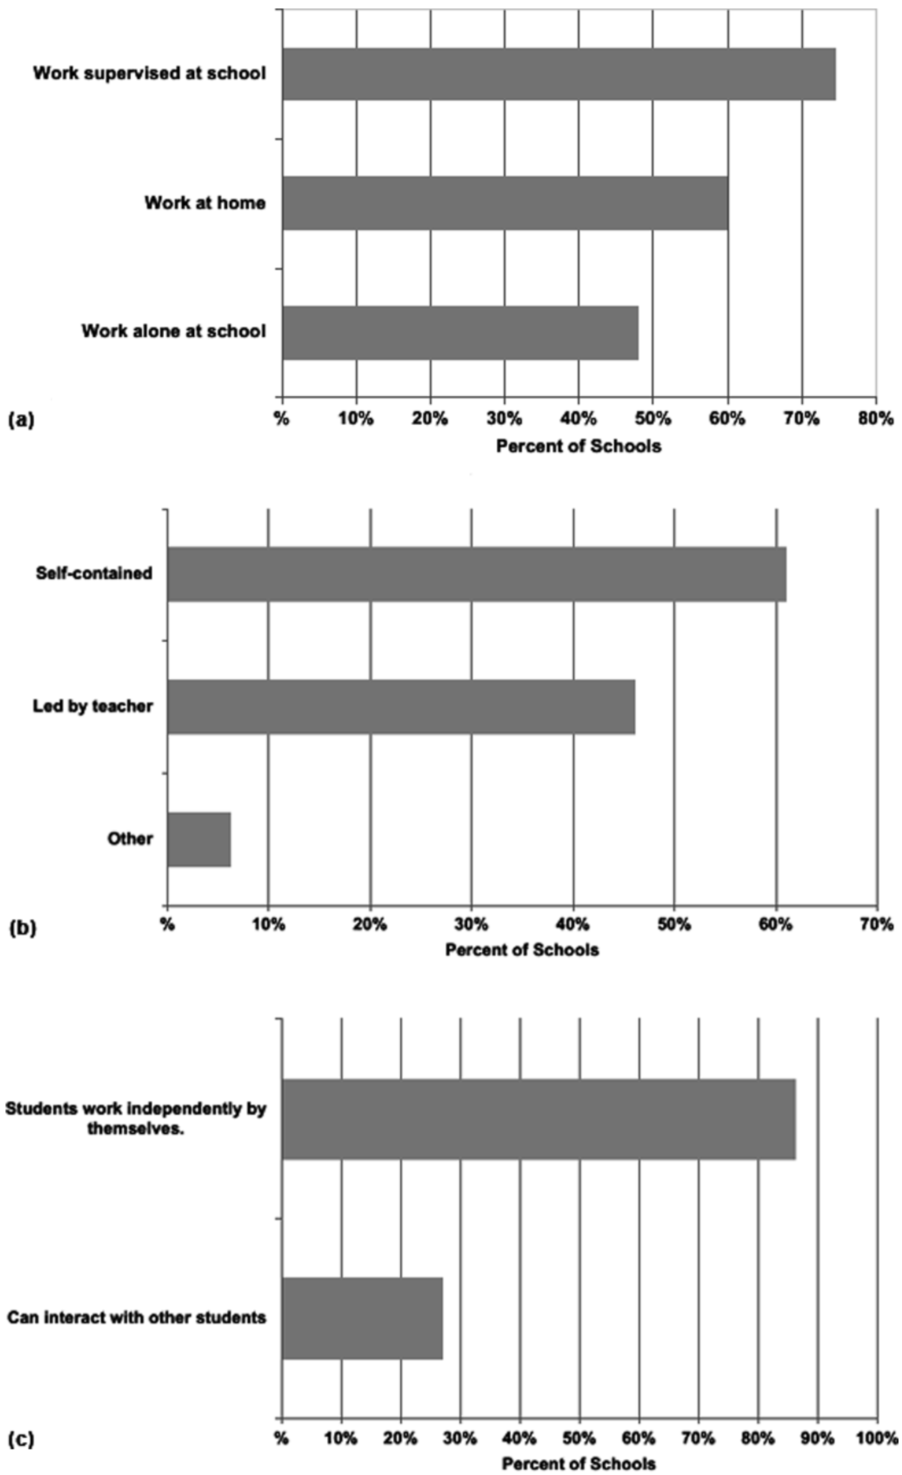
Voices from the Schools

As part of this study, respondents were asked to comment and to offer their voices on any aspect of online or blended learning. Eighty-three principals offered their comments and insights. It is important for the readers of this study to get a feel for the voices of these respondents. The following quotes are presented in an order to provide a balanced view both positive to and expressing concerns about online learning.

Positive Comments

Any time we can enhance the quality of education for our students, we should do so! We are a small school and need to continue offering these opportunities for our kids.

Figure 5. (a) Where students take online courses in Illinois (b) type of online courses (c) type of interaction for online courses



Great for credit recovery and to offer courses not otherwise available at the school.

I believe that online and blended courses are the future of secondary education. Many colleges and universities utilize this type of course, and exposure to these types of courses for college bound students would help them better prepare for their college experience. This may also be a key for reaching students who are independent learners.

Online courses have allowed our higher level students to take college level classes and gain college credit and high school credit at the same time. This opportunity is great for our students and expands our curriculum.

Some students do not learn within the traditional school structure. Offering credit recovery courses via online is going to be an important component for us to graduate more students.

We are a very small rural high school and these type courses allow our students to take more advanced classes and classes we are unable to offer otherwise.

We primarily use technology for credit recovery for students that have failed classes, some students that are homebound, and considering the thought of online courses for foreign language courses.

Expressing Concerns

Whereas these courses are important and teach the use of technology and can expand the curriculum, direct instruction can't be duplicated as far as teaching students the value of face to face communication and contact. Students are losing this skill of interpersonal relationships and communication.

My concern with online courses is that they violate practically every tenet we believe to be true about effective teaching and learning. Research has consistently shown that the quality of the teacher is the greatest determining factor in the quality of a child's education.

Face to face instruction monitors student concerns, problems, and/or impressions about instruction more effectively. Online, seemingly, is more of a "superficial" type of instruction.

Generally, I like them as long as students cannot cheat. They are costly to schools however.

In my personal and professional experiences, including taking some on-line and hybrid courses in my graduate work, the rigor is not there yet. It is also very difficult in and not beneficial for education to limit (correct word) the interaction between pupil and teacher for quality engaged learning and formative feedback.

The real issue is challenging instruction with a union who feels such movement may impact jobs.

My biggest concern would be that if we're going to do something new let's make sure that we do it to the best of our abilities. Right now, with limited or no training, we would not do it correctly and our students would not benefit.

DISCUSSION

Overall Comparison between Illinois and National Samples

In comparing the data in this study with those of a national sample of principals, most of the findings are comparable even though the present study was conducted two years later (2010-2011 academic year vs. 2008-2009 academic year). Online credit recovery courses are proliferating across the country as well as in Illinois. Concerns about costs and course quality continue to dominate the opinions of the principals in both Illinois which are similar to views of administrators across the country. However, these concerns are not preventing the expansion of online learning. Unlike higher education which relies largely on in-house development of online and blended courses, high schools in Illinois and nationally use a number of providers rather than develop courses in house. This is especially true for fully online courses.

Credit Recovery Leads the Way

Credit recovery courses are becoming without a doubt the major type of application for online and blended learning in high schools. In Illinois, the picture supports fully and even shows an acceleration of the use of credit recovery as a means to give students a second chance to complete necessary coursework. The need for these courses varies but relates to students having not completed required coursework earlier in their high school careers due to illness, being homebound, scheduling conflicts, academic failure, and etc. Students needing such courses make up a significant portion of the high school student population that subsequently drops out or is late in graduating. Many high school principals especially those in urban areas are under pressure from state education departments and because of federal mandates to improve student outcomes and to stem the number of drop-outs. When done well, online credit recovery can be a cost-efficient strategy for addressing the drop-out issue mainly because these courses can be purchased on a per student basis as needed rather than funding entire traditional courses taught by a full-time teacher.

While it would be easy to state that the advance of online credit recovery was a positive finding in the study, some caution is needed. The data suggested that while high school administrators are providing more opportunities for students to enroll in online courses, they also have concerns about the quality of online courses and indicate that students need maturity, self-discipline, and a certain command of basic skills (reading and mathematics) in order to succeed in these courses. Many of the students who need to recover credits are those who may not have these characteristics.

Questions have also been raised by teachers and others about credit recovery providing a shortcut to move students quickly through to graduation (Gootman & Coutts, 2010; Winerip, October 24, 2011). The students are happy because they graduate; principals are happy because they improve their graduation rates; and credit-recovery providers are happy because they have increased their profits. However, the students (and their parents) may have been duped into believing that their work was worthy of graduation. One New York City principal stated that: "I think that credit recovery and the related topic independent study is in lots of ways the dirty little secret of high schools. There's very little oversight and there are very few standards." (Gootman & Coutts, 2010) The issue was raised in 2010 and 2011 when nearly 80% of the students entering the City University of New York's (CUNY) community colleges failed at least one basic skills examination in reading, writing or mathematics. Furthermore, the situation was getting worse with more high school graduates or 22.6% of CUNY entrants needing to take remedial coursework in all three basic skill areas, up from 15.4% in 2005. In October, 2011, the New York City Department of Education, using its own set of metrics concluded that 75% of its graduates in 2010 were not ready for college-level work (Winerip October 24, 2011). One observer blamed lax standards, the dumbing down of New York State Regents Examinations required for graduation, and an expansion of credit-recovery programs. David Bloomfield, a professor of education leadership at Brooklyn College, likened credit recovery to "giving out credits like candy…The graduation rate has increased, but without the subject mastery… It amounts to social promotion" (Edelman, 2011).

A local newspaper analysis concluded: "it does the failing kids no favors, either -- turning them loose on the streets wholly unprepared for what they'll face" (New York Post Editorial, 2011).

Online Learning Providers

In earlier national studies of online learning in K-12 school districts, postsecondary institutions and state virtual schools were the major providers of online and blended learning. Both this study of Illinois high school principals and the national study indicate that this has begun to change. While postsecondary institutions and state virtual schools continue to be major providers, independent vendors riding the credit recovery wave are evolving into the number one provider of online learning to high school students in Illinois and many other states especially those that do not have a well-established state-supported virtual high school. Private companies such as Aventa Learning, ALEKS, and EdOptions appear to be providing quality credit recovery programs. In the future, it is likely that these companies will be providing other online courses beyond credit recovery. A major reason for the popularity of outside vendors is that few school districts have the technology or personnel infrastructure to develop high-quality online course content. Outside vendors provide a more efficient way to offer online courses quickly rather than having to invest in a district's capacity to develop their own.

The Pedagogy of Online Learning vs. Graduation Rates

This study provides important insights into the pedagogy of online learning. Principals in Illinois express concerns about the quality of online instruction and at the same time choose to use it more. Some administrators see online learning as beneficial only for "higher-level students," while others view it as "superficial." Regardless, the data demonstrate that online learning especially for lower-performing students via credit recovery is increasing in popularity. As indicated in this chapter, other factors especially the desire to improve graduation rates for all students have pushed educators to use online courses for those most at risk of not completing their high school educations.

The data collected from the Illinois principals also indicate that the pedagogy of online learning is evolving differently in the high schools than, say in higher education, where it has been used for many years. High schools are making greater use of adults (teachers, tutors, other supervisors) to assist students physically in their schools as they participate in online course activities. Students are more likely to be working on their online courses in their school's computer lab or library. This is desirable especially if many of the students enrolled in these courses need extra assistance as might be typical of those in credit recovery courses. The adult in the room can assist both for technical as well as for content or learning issues. This might also be desirable if many of the online courses are not teacher-led, student-to-student interactive environments but are self-contained, programmed instruction type courses where most if not all of the interaction is computer moderated and controlled. Much of the literature on online learning in higher and adult education documents the benefits of student interactions with each other as an important aspect of the benefits of their learning experiences. In the Illinois high schools, it appears that students are not relying on the online course so much as face-to-face contact in school facilities. This needs to be examined further.

Barriers to Online Learning

In addition to pedagogical value, the Illinois principals in this study also expressed concerns about cost, the need for teacher training, and attendance-based funding. Their concerns are similar to those expressed in the national sample. However, their concern about attendance-based funding policies is considerably lower than principals in the national sample. Across the country, funding formulae for primary and secondary education vary from state to state. Some states have not established clear guidelines for funding online courses. The fact that Illinois high schools make significant use of blended learning and use teachers and other adults for supervising online learning students might reduce the concern regarding funding since some face-to-face instruction is still being used.

CONCLUSION

The purpose of this study was to examine the role that online learning was playing in addressing the thoughts, concerns and issues facing Illinois high school principals. Data were collected from a sample of high school principals who were members of the Illinois Principals Association with respect to the extent, nature, and reasons for participating in online learning programs. An important aspect of this study was to compare the findings in Illinois to those collected from a national sample of high school principals. It is our conclusion that online learning and blended learning are making inroads into the high schools in Illinois comparably to those in other parts of the country. The results of this study indicate that online and blended learning are becoming integral to a number of high school reform efforts, especially with regard to improving graduation rates, credit recovery, building connections for students to their future college careers, and differentiating instruction. However, while high schools especially in rural Illinois, are depending upon online and blended learning for many of their programs, concerns remain among administrators about the quality of online instruction. Future study and evaluation should concentrate especially on the efficacy of online credit recovery courses as they continue to evolve into the dominant type of online learning for the students at greatest risk. There need to be assurances that online credit recovery is not being used strictly as a convenient vehicle for improving graduation rates. In sum, the benefits, concerns, and costs related to online and blended learning are prime areas for future research as they become a significant focus in the dialogue on reforming the American high school at national, state, and local levels. Research concentrating on studying these issues is welcome at all levels.

KEY TERMS AND DEFINITIONS

Blended/Hybrid Learning: Instruction that blends online and face-to-face instructional methods.

Credit Recovery: Courses students take to make up requirements needed to graduate.

Graduation Rate: The percentage of students within a cohort who graduate during their expected graduation year.

Online Learning: Instruction provided through online methods.

Online Providers: Companies who provide online course services to school districts.

Rural Schools: Includes districts with average daily attendance of fewer than 600 students, or districts in which all schools are located in counties with a population density of fewer than 10 persons per square mile and all schools served by the districts are located in a rural area.

Virtual Schools: Coursework from an accredited private school or accredited not-for-profit or publicly funded institution, taught primarily through online methods.

Chapter 10
Learning Theory and Online Learning in K-12 Education:
Instructional Models and Implications

Alex Kumi-Yeboah
University at Albany – SUNY, USA

ABSTRACT

Several questions need to be asked about how the applications of learning theories in online learning and how it impacts student learning. Online learning has the ability to promote rapid growth of student academic performance using instructional strategies such as differentiated instructions to meet the specific needs of students. However, less is known about the integration of learning theory and online learning in K-12 schools and its impact on student learning. This chapter seeks to demonstrate the integration of learning theories, online learning and its effects on student academic performance. In this chapter, researchers trace the trend of online learning in K-12 schools, discuss how instructional models are used to promote online learning in K-12 education, and provide discussion on the prospects and challenges facing online learning in the United States. Recommendation for future studies and conclusion are discussed.

INTRODUCTION

Online learning is a form of distance education in which all instruction and assessment are carried out using online, Internet-based delivery (Picciano & Seaman 2009; U. S. Department of Education, 2007). It includes teacher-led instruction and resources designed to instruct without the presence of a teacher in the classroom. Learning and teaching in an online environment are, in many ways, much like teaching and learning in any other formal educational context. Similarities include: learners' needs assessed; content is negotiated or prescribed; learning activities are orchestrated; and learning is assessed (Anderson, 2004). Institutions can use online learning to shape the 'space' and influence learner use.

According to Wicks (2010), about 1.5 million students enrolled in one or more online courses in the 2010 school year in the United States. It is estimated that about 37 percent of school districts in the United States have students tak-

DOI: 10.4018/978-1-4666-8246-7.ch010

ing technology-supported, distance education courses during school 2004/2005 (Zandberg & Lewis, 2008). It should be noted that as of 2012, Alabama, Florida, and Michigan offered full or part-time delivery options to students in grades K-12 (Watson et al., 2010). The National Center for Education Statistics (NCES, 2003) reports that about 62.6% of K-12 students between age groups 3-14, and 72.2% between age groups 15-19, and 59.6% between age group 20-24 have access to Internet.

Increased student population in K-12 schools has created financial constraints for most school districts to cater to the needs of all students; thus, these schools have to find alternative ways to reduce educational costs. This educational environment has increased the desire for online/virtual education for K-12 schools, helping to ease the financial burden as well as reduce problems related to growth in student enrollment (Watson, 2010). Online learning has become popular because of the following reasons: (a) increasing the availability of learning experiences for those who cannot or choose not to attend traditional schools; (b) assembling and disseminating instructional content more efficiently; and (c) increasing student-instructor ratios while achieving learning outcomes equal to those of traditional classroom instruction (Riel & Polin, 2004; Schwen & Hara, 2004). Proponents of online learning argue that it provides students individualized and differentiated instruction with immediate formative feedback about student's performance (Dennen, 2005). This chapter explains the integration of learning theories and online learning and its impact on student learning. In this study, researchers will trace the trend of online learning in K-12 schools, discuss how instructional models are used to promote online learning in K-12 education, and provide discussion on the prospects and challenges facing online learning in the United States. Recommendation for future studies and conclusion will be discussed.

Trends of Online K-12 Education in United States

According to Horn and Staker (2011), about 50 percent of all high school courses will be delivered in an online format by 2019. The International Association for K-12 Online Learning (2012) report estimates that about 275,000 students nationwide are enrolled in full-time, publicly funded virtual schools with a growth trend of enrollment of about 30 percent a year. As of 2012, 27 states have state virtual schools with 740,000 course enrollments in 2012-2013, and 30 states plus Washington DC have at least one full-time online school operating statewide in the 2013-2014 school year (iNACOL, 2013). According to the International Association for K-2 Online Learning (iNACOL), there were 310,000 students enrolled in online programs in the states that serve students from across districts in the 2012-13 school year, which is an increase of 13 percent from the previous year.

According to Keeping Pace (2012), currently 32 states and the District of Columbia offer virtual public schools with 40 percent more enrollments than in the previous year with most of the growth attributed to Florida and North Carolina, which have been aggressively pushing their programs. For example, Florida alone now records more than 220,000 enrollments in its virtual schools. Florida is one of only four states requiring students to take an online course in order to graduate, and allows students to go beyond their local areas and pick online courses from other districts across the state (iNACOL, 2012). According to Watson (2010), individual choice for online courses is likely to increase in the years ahead through ambitious state programs like the one established in Louisiana, as well as through the increasing array of options in existing state and district programs. For example, during the 2009-2010 school year, there were 1,816,400 enrollments in distance education. There are currently 27 state virtual schools, and fulltime online schools in 31 states and Washington, D.C.

With regard to the cost or tuition for enrolling in an online course, the procedures for funding are different in all 50 states. According to iNACOL (2012), many states fund online learning at 30-50% less than traditional education, creating inequity and lack of sufficient support for addressing student characteristics. Currently, the average expenditure for one student is about $6,400 for full online models. Blended learning averages $8,900. This number in comparison to traditional school models average expenditure per student of $11,282 makes online learning less expensive.

Online learning at the K-12 level is highly embraced because the rise of new educational technologies in the 21st century classroom has made the future of K-12 education dependent on online learning. Our classrooms and pedagogical approaches heavily depend on the use of web-based tools aim to promote efficient collaboration and interaction between teachers and students. Interest in online learning will continue to rise in the coming decades, because teachers and students in K-12 schools have access to "virtual spaces" where they collaborate through computers, laptops, mobile devices, and tablet computers. It is estimated that future classrooms will rely on educational technologies to help deliver instructional content, giving students and teachers access to educational materials as well as providing personalized feedback to students about their assessment (i.e., their academic performance).

The tables below depict the numbers of students enrolled in full online courses, state virtual schools, and the percent of students in online class by state. As indicated in Table 1, there are considerable increases in full online school enrollments at the K-12 level from 2008 to 2012 academic school years. For example, online school enrollments in Arizona State increased from 30,076 in 2008-2009 to 39,000 in 2011-2012 with a four percentage change of +30. In Florida there was an increase from 1,079 in 2008-2009 to 9,666; Ohio state online school enrollments grew from 27,037 in 2008-2009 to 35,322 in 2011-2012. In the state of Pennsylvania there was an increase of 22,205 in 2008-2009 to 32,322 in 2011-2012. However, the number of students in online schools in Kansas decreased from 3,100 in 2008-2009 to 2,952. Additionally, states such as New Hampshire, Louisiana, Tennessee, and in certain years for Washington, and Massachusetts did not provide data on online school in K-12 schools.

Table 2 shows state virtual schools and the number of course enrollments in the 2011 to 2012 academic year. As seen in Table 2, Florida had the most number of course enrollments at 303,329 in 2011-2012, followed by North Carolina (97,170); Alabama (4,332); Georgia (20,876); Michigan (19,822). States such as Colorado (1,564); Missouri (1,562); Iowa (1,431); and Vermont (769) had the least number of course enrollments.

Table 3 depicts a sampling of states with prominent virtual schools in the 2012 academic year. Florida virtual schools had the largest course enrollment of 303,329 with an annual growth of 17% followed by North Carolina at 97,170 with annual growth of 10%; Alabama ACCESS 44,332; Georgia virtual school 20,876; Michigan virtual school 19,822; Idaho digital learning 17,627; South Carolina 15,831; New Hampshire virtual learning academy 15,558; and Montana digital academy with the least growth of 6,797.

Table 4 reveals sample of state with state virtual schools that have remained small in 2012 school year. State virtual schools in Connecticut, Illinois, Texas, and Kentucky all had negative annual growth rates.

Table 5 shows states with multi-district, full online schools in 2012-2013. States such as Arizona, California, Ohio, Pennsylvania, Florida, Colorado, and Georgia had a significant number of course enrollments for the 2012-2013 academic year, while Virginia, New Hampshire, Massachusetts, Iowa, New Mexico, Alaska, and Arkansas received minimal course enrollments.

Table 6 shows state-supported, supplemental options for 2013 school year. States of Florida, North Carolina, Alabama, Michigan, and Idaho

** Total student population 2009-10, National Center for Education Statistics, http://nces.ed.gov/programs/stateprofiles/ AZ, CO, and OK are unique student counts of both full- and part-time students. AZ 2011-12 enrollment data is an estimate. CA data source changed from 2011; 2010-11 data is an estimate. IN numbers include some blended schools run by national EMOs. KS and WA started separating FT enrollments in its most recent year's reporting; previous years are estimates of FT users based on the same percentage of the unique student count. WA 2011-12 enrollment data not yet available and MO was removed from FT table because the majority of full-time enrollments are private pay.

Table 2. State virtual schools and number of course enrollments in school year 2011-12

State	Number of Course Enrollments
Florida	303,329

to 2004-2005 (37%), to 2009-2010 (55%). The number of students in all instructional levels also increased from 317,070 in 2002-03 to 1,816,390 in 2009-10. As seen in Table 7, students at elementary schools in distance education/online learning increased from 2,780 to 78,040 (from 2002-03 to 2009-10); 6,390 to 154,970 in 2002-03 to 2009-10 for middle grades or junior high schools; 214,140 to 1,348,920 in 2002-03 to 2009-10 in high schools; and at combined or graded schools student population increased from 93,760 in 2002-03 to 234,460 in 2009-10. There was a significant increase in the number of student in poverty concentration taking online learning in 2009-10 academic year.

Table 6. State-supported supplemental options 2013

State	SVS Enrollments 2012-13	SVS Annual Change	State Supplemental Options Factor

continued on following page

As indicated earlier, most states have adapted online learning at the K-12 level as a measure to reduce the ratio of teacher-student and to promote collaboration and effective teaching of content of subject matter. Online learning serve as a way to reduce the cost of providing education to the increasing population of students in K-12 schools. Many school districts are struggling to fulfill the specific educational needs of students due to financial restrictions and other budgetary allocations. Data shows that online learning is growing in popularity, thus, providing an opportune time for teachers, educators, administrators, and policy makers to devise ways to train new and existing teachers on best practices and strategies for teaching online courses. Teachers must be trained on the effective use of learning management system and introduced to online teaching certification programs for pre-service teachers in colleges of education. Unfortunately, online teaching experience can feel like starting over for many teachers. Teachers must get formal structures as well as informal connections. Additionally, various school districts must equip and train administrators in order to understand online learning and blended instruction.

‡Reporting standards not met. The coefficient of variation (CV) for this estimate is 50 percent or greater.

\1\Based on students regularly enrolled in the districts. Enrollments may include duplicated counts of students, since districts were instructed to count a student enrolled in multiple courses for each course in which he or she was enrolled.

\2\Combined or ungraded schools are those in which the grades offered in the school span both elementary and secondary grades or

NOTE: Percentages are based on unrounded numbers. For the 2002–03 FRSS study sample, there were 3 cases for which district enrollment size was missing and 112 cases for which poverty concentration was missing. For the 2004–05 FRSS study sample, there were 7 cases for which district enrollment size was missing and 103 cases for which poverty concentration was missing. Detail may not sum to totals because of rounding or missing data. Some data have been revised from previously published figures. Standard errors appear in parentheses.

BACKGROUND

Vygotsky, implied through his theory that "cognitive development and the ability to use thought to control our own actions requires first mastering cultural communication systems and then learning to use these systems to regulate our own thought process" (Cavanaugh et al., 2004, p. 7-8). Vygotsky contended that learning takes place for children when they are working within their zone of proximal development. Tasks within the zone of proximal development are ones that children cannot do alone and thus need or seek the guidance or assistance of their peers or adults (Cavanaugh et al., 2004).

Constructivism was further developed through the works of Bruner, Vygotsky and Papert (Neo, 2007). Vygotsky's fundamental contribution to constructivism was the formal introduction of a social aspect to learning. Constructivism, a learning theory that is widely used in distance learning, is founded on the premise that "by reflecting on our experiences and participating in social dialogical process we construct our understanding of the world we live in" (Cavanaugh et al., 2004, p. 8). According to Wang (2008), in an educational context, pedagogy often refers to the teaching strategies, techniques or approaches that teachers use to deliver instruction or facilitate learning (p. 412). Constructivism, stated simply, contemplates how the learner constructs knowledge in a meaningful way. According to Hoci-Bozic (2009), the educational system includes "elements of behaviorism, cognitivism, and constructivism"; however, "constructivism is the most widely accepted model of learning in education today" (p. 21). The constructivist school recognizes the learning as an active process of constructing meaning and where students construct own versions of the learning matter (Hoci-Bozic, 2009). Gulati (2008) contend that learning theories in online content are often termed as "socially constructivist experience" because students are actively communicating with one another through an online medium or as a result of blended online and traditional classes (p. 184). In social constructivism, "individuals make meaning in dialogues and activities about shared problems or tasks" (Helland, 2004, p. 619). It offers students the chance to dialogue with their peers. Cavanaugh (2009) states, "only students who were typically successful in online learning environments were those who had independent orientations towards learning" (p. 13). In addition, students were most successful when they had "strong time management, literacy, and technology skills" (Cavanaugh, 2009, p. 21). Web-based technology offers many opportunities to expand on students' conceptual and experiential backgrounds (Cavanaugh et al., 2004).

In 1957, Jean Piaget (1957) proposed cognitive constructivism as the process through which students learn by interacting with the environments in which they find themselves. He described cognitive processing of environmental interactions and the construction of mental structures to make meaning of what they learn. Jean Piaget called these mental structures schema that occurs through the processes of assimilation and accommodation. Assimilation is the process through which new knowledge is incorporated into existing schemas. In accommodation, new knowledge conflicts with existing schemas that eventually must be altered to incorporate it. For example, Piaget stated that:

Fifty years of experience have taught us that knowledge does not result from a mere recording of observations without a structuring activity on the part of the subject. Nor do any a priori or innate cognitive structures exist in man; the functioning of intelligence alone is hereditary and creates structures only through an organization of successive actions performed on objects. Consequently, an epistemology conforming to the data of psychogenesis could be neither empiricist nor preformationist, but could consist only of a constructivism. (Piaget, 1980, p. 23)

Based on the above theory, social constructivism reminds us that learning occurs through social activity, that is, student knowledge is constructed through communication, collaborative activity, and interactions with others that occur whenever students enroll in an online class. One of the major tenets of constructivism theory is the social aspect of learning. Online learning for K-12 students provides opportunity for students to construct knowledge through discussion forums, interacting with teachers, and peers, using learning management systems and others. Instructional models allow students in online classes to engage learning as an active process through which students construct their own versions of the subject matter or content by using online discussions or working in groups as stated by Hoci-Bozic (2009). Cognitive constructivism locates learning in the mind of the individual as well as promotes learning as an active process of mental construction that is linked to interactions with the environment. Thus, student interaction in an online class helps trigger construction of knowledge through interrelated process of assimilation and accommodation. It also helps students in an online class to naturally organize and construct knowledge. The inclusion of constructivism in online learning models facilities communication by allowing students to present their beliefs and products to broader audiences. Constructivism in online learning exposes students to diverse opinions of people in the real world beyond the classroom, school, and the local community.

Online Learning in K-12 Environment

According to O'Dwyer, Carey and Kleiman (2007), K-12 students in online instruction outperformed their counterparts in the traditional face-to-face instruction. The study used quasi-experimental design to compare the learning of students participating in Louisiana Algebra 1 Online initiative with the learning of students in comparison classrooms with similar mathematics ability, environment, and size. In a quasi-experimental study conducted by Rockman et al. (2007) to evaluate the effectiveness of Spanish courses offered to 463 middle school students (seventh and eighth graders) in the West Virginia Virtual School System, researchers employed a blended model of instruction that combined face-to-face and virtual instruction with Web-based activities. A three-member teacher team consisting of a certified Spanish lead teacher designed and delivered lesson plans as well as conducted weekly conversations with students. Another certified Spanish teacher, an adjunct, provided content-related feedback through e-mail and voice-mail, and graded students tests and quizzes. The third teacher, a non-Spanish certified classroom facilitator, guided students both online and offline to complete assignments and projects on time. In this study, the blended learning component was offered in 21 schools with inadequate resources to provide face-to-face Spanish classes for students. Face-to-face group instruction included seven schools with adequate resources for virtual schools, specifically in regards to language arts achievement and school size. The results indicated that students in the face-to-face instruction performed significantly higher than those receiving instruction in the online blended section of the course.

In contrast, a study conducted by O'Dwyer, Carey and Kleiman (2007) using quasi-experimental design methods to compare students' mathematics ability in a fully online Algebra class (seventh and eighth grades) with students in a traditional face-to-face instruction yielded different results. The findings from a comparison of 463 students (231 seventh and eighth graders from the treatment group, 232 seventh and eighth graders from the comparison group) indicated that students in the online program performed better than those in the traditional face-to-face classrooms.

Similar findings were observed in a study designed to examine the effectiveness of virtual Web-based learning as compared to traditional face-to-face instruction in a science laboratory class with 113 fifth-grade students in Taiwan (Sun, Lin, & Yu, 2008). The study utilized a quasi-experimental method that included a treatment (56 students) and a controlled group (57 students) in four classrooms from two randomly sampled schools. Students in the treatment group used the virtual Web-based science lab time and conducted virtual experiments and projects with teacher supervision, while students in the control group performed similar science experiments using traditional face-to-face lab equipment. Results from the study reflected a higher performance for students engaged with the virtual Web-based lab as opposed to those in the control whose experiments involved traditional lab equipment.

INSTRUCTIONAL MODELS (THEORY) AND ONLINE LEARNING IN K-12 EDUCATION

In the 21st century, teachers are expected to be creative and innovative in order to deliver instruction to meet the needs of students. One of the instructional approaches that can be use is the inclusion of technology in their lessons. Instructional models serve as guidelines or strategies that teachers can use as their instructional approaches. The time has come for teachers to use instructional models in online learning in K-12 schools. Instructional models in online learning serve as a principal guide for teachers in the development or re-design of courses for K-12 learning environments.

According to Patrick (2011), the New Models Using Online and Blended Learning TPAC framework developed by (iNACOL) is one of the instructional models that can be used in K-12 school settings. With this model, the student is at the center with support from each of the elements. Technology represented as (T) in the model forms an important core element in the model; the "P" represents people, new pedagogical models, and professional development to transform the old traditional system into an engaging student-centered models.

The "A" represent assessment and "C" embraces online content or course information. Overall, the new models using blended and online learning TPAC framework operates as (a) Technology platforms – this consists of enterprise architecture which involves the design of courses, learning management system comprising of the virtual learning environment, teacher to student interaction online, technicalities or technical know how of broadband Internet infrastructure, and instructional models as related to standards-based and competency-based approaches to student learning and performance; (b) People/Pedagogy – this part of the model encompasses the need for teachers to acquire new skills to be able to teach online, the need for administrators to understand and use new skills to manage online programs, the ability to response to intervention models (RTI) through online or blended learning, and the idea of personalizing instruction that allows students to learn at their own pace; (c) Assessment –this include online/adaptive assessment tools to be used to assess students as well as performance-based principles; and (d) Online Content – this consists of online courses, dual enrollment, credit recovery, and common core curriculum for students in K-12 schools.

The TPAC framework comes with design principles of new learning models based on a 2013 iNACOL survey on online and blended learning in K-12 education. The design principles of the new models are categorized into personalized, student-centered, opportunities for inclusion, high performance, technology-enhanced, sustainable at scale, innovative educator roles, and demonstrating competency.

The personalized section in the model comprised ten essential components of personalization as: (1) student agency (student has voice and choice on level of standards/lesson and some control over how they learn); (2) differentiated instruction; (3) immediate instructional interventions and supports for each student is on-demand, when needed; (4) flexible pacing; (5) individual student profiles (personalized learning plan); (6) deeper learning and problem solving to develop meaning; (7) frequent feedback from instructors and peers; (8) standards-based, world-class knowledge and skills; (9) anywhere, anytime learning can occur; and (10) performance-based assessments, such as project-based learning and portfolios of student work.

The student-centered section includes: (a) learning environments that respond to each student's needs and interests, making use of new tools for doing; (b) embracing the adolescent's experience and learning theory as the starting point of education; (c) harnessing the full range of learning experiences at all times of the day, week, and year; (c) expanding and reshaping the role of the educator; and (d) determining progression based upon mastery.

In addition, the opportunities for inclusion section consists of the ability of teachers to: (a) meet the individual learning needs of each student, including students with disabilities; (b) engage in equally or more rigorous learning opportunities for students; (c) provide multiple methods of instruction (context, content, and instructional methodology) to ensure that students from different cultures and life experiences have the opportunity to succeed; and (d) ensure digital content is designed using the principles of Universal Design for Learning (UDL) so that the content is accessible to all students.

Higher performance comprises the following: (a) use competency-based models to ensure student mastery; (b) utilize data to drive instruction through the analysis of frequent and varying forms of assessment; (c) apply valid and reliable assessments in ways that are meaningful to students; and (d) assess students on their performance in multiple ways and multiple times to ensure they have reached proficiency (i.e., the implementation of adaptive assessments, formative assessments, imbedded assessments, performance-based assessments and summative assessments).

Technology provides opportunities for students to collaborate with teachers and peers, unlimited by proximity. Students engage with digital content, which can occur anytime, anyplace, and have multiple pathways that are competency-based and not tied to a fixed school calendar. In addition, technology integrates student information and learning management systems designed around competency-based approaches, providing data to support students, teachers, and schools for improving performance.

Sustainable at Scale includes (a) approaches to add productivity and value to ensure cost-effectiveness. (It is important to monitor the relationship between results and services and spending in order to be effective); (b) integration of blended and online learning into essential K-12 education funding process; (c) allowance of funding to follow students down to the course level; (d) performance-based funding that may tie (at least part of) K-12 funding to student growth, rather than "seat time"; (e) use of public and private partnerships to achieve efficiencies and avoid "re-inventing the wheel"; and (f) new learning models that are sustainable on recurring public revenue after four years of launching and implementation.

The innovative educator roles section of the model presents the following elements: (a) teachers "[coordinating] student learning" through the expanded use of technology-based tools and content, as well as the effective use of outside experts, out-of-school and/or community resources; (b) environments providing flexibility to mix schedules of online and physical instruction and with a highly flexible schedule, instruction and learning; (c) structures (e.g., online tutoring, home mentors, and technical support services) supporting 24/7 in addition to teacher support; (d) revised human resources policies including a team approach to educating students, shifting educator roles, with reconsidered expectations for teaching staff to have greater expertise in instruction and assessment, and greater flexibility in hiring; and (e) adequate support for educators including integrated student information and learning management systems, coaching in instruction and assessment, and opportunities for educators to build a common understanding of proficiency.

The last part of the new model is demonstrating competency, which includes: (a) academic and efficacy standards; (b) structured learning objectives so that they are explicit and measurable; (c) alignment with standards benchmarked for college readiness and success after high school, such as Common Core State Standards, college entrance requirements, or globally-benchmarked standards; (d) outcomes Include Understanding and Application of Knowledge, Skills, and Dispositions Through Demonstration of Deeper Learning and Evidence Toward College and Career-Ready, World-Class Standards; and (e) rigorous, developmentally appropriate content based on the science of learning (Sturgis, Rath, Weisstein, & Patrick, 2010).

Instructional models could be adapted to part of the K-12 online learning curriculum as it provides for students the ability to construct knowledge at their own pace. The instructional models allow teachers to design a variety of methods to support the learning needs of students such as English language learners, students with disabilities, and gifted students. As stated in the literature above, online learning in K-12 education allows students to progress at different paces. The use of instructional models in K-12 online education allow teachers to design courses that make room for students to personalize their learning with specific individual student's interests and provide opportunity for teachers and students to maximize time. For example, teachers could design online learning models to transfer activities such as test preparation and class activities teacher-based to independent online learning activities.

Based on the above models, it is important for teachers and administrators as well as other leadership in K-12 education to prepare and develop instructional approaches in online learning. In the context of online instruction, teachers could design instructional process to involve students in the learning process and assess their progress to meet instructional objectives as stated in the literature about cognitive and social constructivism. Teachers using online instructional model must be aware that knowledge is not constructed in isolation; rather, students must be given the opportunity to interact with their peers for knowledge to be constructed. Teachers should lead students towards construction of new knowledge in order to increase students desire to learn on their own.

PROSPECTS

As indicated above, online learning has come to stay in K-12 schools. In the 21st century we cannot deny the existence and use of online/virtual learning in K-12 schools. For example, as a result of the growing trend of online course enrollments and active participation of teachers and administrators in K-12 schools, online education in K-12 schools is increasing across statewide with most states implementing online teaching certification for teachers. Online education has proven to be viable to both teachers and students as it is a viable way to enhance the curriculum by providing live events such as online homework help as well as the convenience it creates for both teachers and students.

Online education provides opportunity for students to engage in learning and meaningful dialogue among students. For example, students can use communication tools such as IM or e-mail through a chat room to work together to complete class project assignment. A constructivist approach to online course design has distinct advantages over other types of approaches, but it is important to focus on the approach when designing online content. One of the strengths of online learning is that it allows diverse learners to communicate without necessarily being in the same building or even the same country. A teacher that can establish and manage this type of learning environment can see the benefits for students as they interact with their peers in constructing knowledge. Students are able to interact and experience a variety of media from online resources and computer simulations. These resources, coupled with the interaction of the other students, leads students through the course as their new knowledge is infused with prior knowledge. Through online discussion and interactions, students can construct meaning with others in the course. Thus, such environments enable students who are mostly quiet in class to be active participants in online discussion forum, especially English language learners and students with certain form of disability.

Online learning has the potential to help students in rural schools by broadening the educational courses available to them through online classes. Students can communicate with experts in the field. Online collaboration also enables underrepresented population to contribute in equal proportion with their peers (Anderson & Lin, 2009).

Online education creates the opportunity for some school districts that are facing financial or budgetary allocation problems to have access to open education resources that enable teachers and students to access and use textbooks and other educational resources online. This helps school districts, facing financial problems, save money. Online classes offer a more flexible and personalized form of education, allowing students to progress at their own pace and on their own time. For example, it provides an extensive course structure and quality far beyond what many school districts can provide for students. It also creates flexibility in course scheduling for students by extending learning via digital world, which is available in 24 hours a day, seven days of the week. Online learning offers K-12 students feedback and communication about their performance. Communication tools such as discussion boards and chat rooms in online learning can be effective in inter-team collaboration as well as in teacher-student communication. The use of online assessment at the K-12 level allows efficient data collection about individual and group performance that would be difficult to collect in the traditional classroom. For instance, online quizzes and tests give students and teachers instant feedback about their scores. Teachers do not have to go through the long process of calculating grades or quizzes.

Online learning has the potential to help students in rural K-12 schools where funding may limit students' access to varied courses. Online education and resources provide opportunity for students who live in rural areas, allowing them to receive the same educational resources as students in urban areas. Online learning provides students learning resources that they can use for homework and other individual class projects. Furthermore, the rising costs of books and cash-strapped budgets in K-12 schools have made most school district in the country rethink the use of online textbooks, thus leading to the rise of open educational resources (OER). The OER creates a smooth and efficient pathway in delivering engaging and up-to-date content to students. This method has proven to be cost effective as compared to paper-based textbooks for students and teacher.

CHALLENGES

Online education in K-12 schools has contributed immensely to the teaching and learning process by providing many students access to a high school education and diploma. It promotes student-centered learning, provides access to dual credit and advanced placement courses for college credit, and offers K-12 students the opportunity to engage in technology as part of their learning. However, it comes with some challenging experiences for students, teachers, administrators, and policymakers in the school system. For example, Payne (2008) states, "the danger that student-to-student interaction will be stifled or overwhelmed by instructor/facilitator postings is real" (p. 158). Instructor needs to find a balance between being available for communication and answering questions, but also be aware of how much they are contributing or leading the discussion. Students should build their own knowledge by using class resources more than relying wholly on the instructor.

Developing such programs often proves difficult as online communities of students and teachers try to take root in school systems that have long operated brick-and-mortar schools at local taxpayer expense and with local school board control. According to Watson (2010), funding of online learning for students at the K-12 level in several states is a major issue. Watson (2010) further explains that it is due to the fact that online schools sometimes draw students across district lines, and funding often follows the student. Thus, students leave "home" school district for the online school, resulting in a drop in funding for that school district.

More so, online courses can pose challenges for students with learning or physical disabilities. It may be difficult for some students with learning or physical disabilities to access Internet use independently without any help from teachers or parents. It is evident that certain students with learning or physical disabilities may not be able use technology and communication tools involved in blended and online learning at the K-12 level (e.g., online discussions, blogging, chats, and simply the use of emails or telephone). Lack of qualified instructional technology staff is a major challenge to managing successful blended learning program. A typical example is that of shortage or lack of IT staff in states like Louisiana, Georgia, and Florida (Project Tomorrow, 2010). Few instructional staff members are offered trainings on technology or how to teach online. Further, in 2010 only 12% of new teachers reported receiving college or university training on online education (Dawley, Rice, & Hinck, 2010).

Additionally, the rising growth in online education has outpaced education policy in several states (Watson, 2010). For example, in many states such as Florida, Alabama, Georgia, Ohio, and California online programs are guided and overseen by rules and regulations created for traditional schools. According to Watson (2010), in 2001 the National Association of State Boards of Education stated, "In the absence of firm policy guidance, the nation is rushing pell-mell toward an ad hoc system of education that exacerbates existing disparities and cannot assure a high standard of education across new models of instruction" (p.12). Finally, even advocates of online education say that online learning is not for everyone. It requires a certain degree of self-motivation, and the active participation of a parent or some other adult to help with classwork and ensure that a student is on track. Despite the rapid growth during the past decade, only a small fraction of students in the country take even one class online. In fact, observers do not expect digital classrooms to replace the neighborhood school anytime soon.

RECOMMENDATION FOR FUTURE STUDIES

A forecast growth of online learning in K-12 schools continues to increase across states in the present realm of technology. It is estimated that there are 1,816,400 enrollments in distance-education courses in K-12 school districts in 2009-2010 with a high percentage being online courses. In 2013, it was estimated that approximately more than two million, K-12 students took an online learning course (iNACOL, 2013). Thus, a critical look at the trend of online learning will concluded that it has transform America's education system as a means to provide additional support and means of personalized learning approaches for all students (Watson, 2010).

Due to this evidence, the author proposes an investigation using quantitative research methods to test the various learning theories at all instructional levels, determining which one will best suit students in K-12 schools. Another investigation could be conducted via participatory action research to determine the effectiveness of a particular learning theory on student learning and also to determine which aspect of the instructional model discussed above could be adopted without any challenges in the classroom setting. Furthermore, there could be a qualitative study interviewing K-12 school students, teachers, and administrators about the benefits and challenges of using a particular learning theory in an online learning paradigm. This could help to assess the effectiveness and use of an instructional model and its implications on students in online learning.

A longitudinal study could also investigate the trend of learning theories in online learning environments at K-12 level on students and teachers.

CONCLUSION

Online learning has come to revolutionize instructional delivery to K-12 school students. As indicated above, online learning takes place in different dimensions to augment effective teaching and learning process. Several instructional or teaching models have been combined to implement successful online environments for K-12 students. The most commonly used is constructivism in which students get the opportunity to construct knowledge via social interaction online with their peers. Online learning can benefit K-12 students by providing a wider range of courses that many traditional schools cannot offer students. This can allow the opportunity for some students to graduate early or recover credits from classes they have failed or need to take; the ability to extend learning in a digital format to help students learn, and the availability of coursework 24 hours a day, seven days a week. It is therefore imperative on the part of teachers, students, and administrators at the K-12 school system to embrace the use of online learning and promote its effective implementation, because of its increased use across all levels of education in the United States.

KEY TERMS AND DEFINITIONS

Blended Learning: A form of distance learning that combines different forms of instructional technology (e.g., videotape, CD-ROM, Web-based learning, e-mail, telephone, & chats, blogging) with traditional face-to-face instructor-led instruction depending on availability, access, and resources in the context of location, time and space.

Constructivism: Constructivist learning is based on students' active participation in problem-solving and critical thinking regarding a learning activity which they find relevant and engaging. They are "constructing" their own knowledge by testing ideas and approaches based on their prior knowledge and experience, applying these to a new situation, and integrating the new knowledge gained with pre-existing intellectual constructs.

Face-to-Face Instruction: Is a form of instruction that requires teachers and students to single location (classroom) with a fixed amount of time for interaction between instructor and students at a specified time in a particular place and time (classroom).

Instructional Models: Are guidelines or sets of strategies on which the approaches to teaching by teachers are based. They are based on learning theories. Learning theories describe the ways that theorists believe people learn new ideas and concepts.

Instructional Technology: Instructional technology consists of the design, development, utilization, management, and delivery of instruction either through media, electronic, print and other technology (computers, audiovisuals and equipment) as well as the evaluation of instruction for learners.

Learning Theory: Learning theory is a model of psychology that explains human responses through the concept of learning. Learning theory includes behaviorism, cognitive theory, cognitive-behavioral theory and constructivism.

Online Learning: Is a type of learning where access to learning experiences occurs through the use of technology. Online learning can be "Fully or Wholly" online or can be described as learning in reference to technology medium or context with which it is used.

Chapter 11
Factors Shaping Academics' Use of Technology in Teaching: A Proposed Model

Geraldine Torrisi-Steele
Griffith University, Australia

ABSTRACT

Whilst academics have generally adopted the use of new technologies in their teaching, literature indicates that only a minority is exploiting technology to provide pedagogically rich learning experiences. This is a significant issue for universities, many of which are making considerable strategic investment into technology-infused teaching, as one way of responding to the pressures of globalization and meeting the needs technology-savvy student cohorts. Providing appropriate support to assist academics to implement effective, technology-infused teaching strategies is thus critical. It is argued that development of appropriate academic support should be informed by an understanding of why academics use technology as they do in their teaching. Towards this end, a model of factors influencing how academics use technology in their teaching is proposed in the chapter. The model arises from a synthesis of relevant literature and the identification of pertinent conceptual frameworks.

INTRODUCTION

New and emerging technologies have rapidly become a major feature of higher education teaching contexts. However, although institutions are making considerable investment to promote and support the use of technology in teaching, literature indicates that effective technology infused teaching practices are being adopted only by a minority of academics (Graham & Robison, 2007). Hence, a major challenge for higher education is supporting university teaching staff so that, post-adoption of technology, their use of technology will extend beyond purposes of efficiency and access, to the provision of pedagogically rich learning experiences.

In effort to lay some foundation for much needed further research aimed at addressing the issue of how to support academics in their use of technology-infused teaching, the chapter develops a model of factors that potentially influence how academics use technology in their teaching.

DOI: 10.4018/978-1-4666-8246-7.ch011

The model is developed by, first exploring and synthesizing existing literature, and then identifying noteworthy factors arising from literature and pertinent conceptual frameworks(technology acceptance (Davis, 1986), evolution of teaching practice (Sandholtz, Ringstaff, & Dwyer, 1997), teaching style (Grasha, 1996) and constructivist philosophy (Jonassen, 1994), and technological, pedagogical and content knowledge (Mishra & Koehler, 2006), and self-efficacy (Bandura, 1986).

It is envisaged the chapter will be of interest to university administrators developing support mechanisms and strategies to promote institution-wide adoption of effective technology infused teaching practices, to those engaged in the provision of professional development for academic teaching; and to researchers in the field of technology and pedagogy in higher education. The chapter provides a launching point for much needed further research into identifying factors shaping the manner in which academics' use technology for teaching.

BACKGROUND

Today's universities are compelled to change as they face what is possibly the most significant challenge in their history. The source of the challenge, as Siemans and Matheos (2010) so neatly sum up, is that at the same time as universities grapple with emerging technologies and the challenges of delivering education in a form palatable to a technologically savvy student body, the forces of globalization, expansion, and economic uncertainty are bearing down on institutions.

The potential of technology infused teaching approaches to help universities cope with current pressures is widely acknowledged in the literature. Many universities are investing considerable effort and money, to support institution-wide use of efficient, flexible, and quality technology-infused teaching strategies (Bonk, Kim, & Zeng, 2006; Graham & Robison, 2007; Garrison & Kanuka, 2004; Graham, 2006; Vasileiou, 2009). Technology use in teaching contexts clearly offers the advantages of flexibility and efficiency, which help universities, cope with increased student numbers and varied student needs. Furthermore, the use of technology may be a 'draw-card' for today's technology savvy students. Many students coming to university are immersed in new technologies and live in a highly connected social network and there is an expectation that the technologies with which they interact on a daily basis will also be present in their learning environment. Courses meeting these expectations will be more attractive to students (Ross & Gage, 2006). Technology also offers flexibility of access (through remote collaboration) for the increasing numbers of students juggling study, work and family (Uğur, Akkoyunlu, & Kurbanoğlu, 2011).

Although efficiency and flexibility are important considerations, alone they will not enable a university to remain competitive in the global market. As Graham and Robison (2007) point out, the promise of technology rich learning to help universities change in response to pressures will only be realized by the widespread adoption of effective technology-infused teaching practices.

Proponents of using technology for teaching, argue that technology can be used not only to create effective learning experiences, but that it offers some pedagogical advantage over more traditional methods for a number of reasons - it can facilitate the building of communities of inquiry, it offers the opportunity to provide experience that might not otherwise be possible, it more strongly focuses attention to the teaching and learning and so promotes the design of user-centered learning experiences, and it can encourage engagement and develop self-directed learning skills in students (Garrison & Kanuka, 2004; Sancho et al. 2006; George-Walker & Keeffe, 2010).

It is important to highlight at this point, that at the crux of views of pedagogical potential of blended learning is the academic's ability to create effective, pedagogically rich, experience through the appropriate use of technology together with face-to-face strategies. It is not the technology, per se, that has the power to transform learning for the better. Rather, this power rests with the academic.

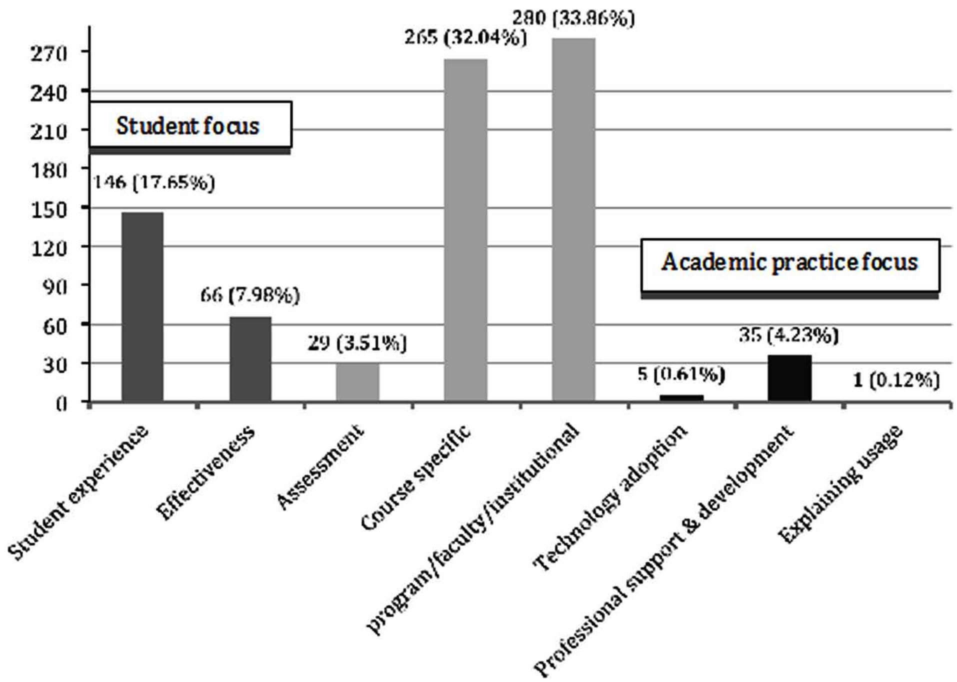
However, for many academic, harnessing the potential of technology with face-to-face teaching to transform learning for the better poses significant challenge. Firstly, academics need to build a body of knowledge of what technologies are available and to identify the capabilities of each technology - difficult tasks when new technologies are emerging at a rapid rate. Add to this that academics need to acquire knowledge about what technologies their university's infrastructure supports and how they can be technically implemented. Finally, academics then need to be able to map the attributes of both face-to-face teaching and the available technology to the requirements of the task and learning objectives so that they will be able to re-design courses with the appropriate learning activities. This usually involves significant redesign of courses.

Considering the demands facing academics intending to implement technology infused teaching approaches, it is not surprising that the achievement of widespread adoption of effective practices is proving difficult, with the vast majority of implementations having little or no impact on practice, at best, merely "stretching the mould" (Collis & Van Der Wende, 2002, p. 7), using technology for reasons of administrative efficiency and provision of supplementary access, but generally not providing, more effective pedagogically enriched learning experiences that are so essential for engaging and keeping today's technologically savvy student body. Herein, then, is a key issue for higher education: how can academics be supported to facilitate the widespread adoption of not only efficient, but also effective technology-infused practices?

It is now argued that an important pre-requisite for addressing the aforementioned issue is knowledge about factors influencing how academics are currently use technology in their teaching. As adult learners, academics will have developed a mental model about teaching with technology, that is, "assumptions derived from past beliefs and experience and expectations about future behavior and events crafted by these assumptions" (Thornton, 2008, p. 1040). When dealing with new tasks, the mental model is invoked and has an impact on how the new task is accomplished. Thus, to change technology infused teaching practices, academics need to redefine their mental models about teaching and learning and the role of technology (Brancato, 2003, p. 63). In order to redefine their mental models, academics first need to make the connection between new knowledge and their existing practice (Cranton & King, 2003). From this perspective, the role of professional support and development must be to effect connection to existing teaching practices, facilitate reflection and, subsequently nurture transformation in practice so that technology is used to develop effective technology infused teaching practices. Hence, knowledge of factors influencing academics' current practices is an important pre-requisite to formulating the support needed to help academics develop pedagogically rich technology-infused teaching practices.

However, the body of knowledge relating to factors influencing academics' use of technology for teaching is limited. A literature search conducted by the author supports this view by showing literature seeking to identify factors influencing how academics use technology in their teaching is very sparse. The search was conducted using Thomson Reuters' Web of Knowledge was conducted with the key words ((blended learning OR hybrid learning OR learning technology OR blended teaching) AND (university OR higher education OR academics OR faculty)). Thomson Reuters' Web of Knowledge provides access to a large volume of literature, from varied sources (over 12,000 of the highest impact journals worldwide, including Open Access journals and over 150,000 conference proceedings" (Thomson Reuters, n.d, para. 1)) and thus represents a substantial cross-section of literature.

Figure 1. The count of papers in each of the subcategories of research interest



The search identified 827 relevant to the use of technology in university teaching. When each of the 827 articles was then examined to identify the aim or dominant theme of the reported research, the results could be sorted into broadly into three topic areas identified in the initial literature search, each broad topic area could be further classified into subtopics (figure 1).

Of the 827 papers resulting from the search, only one (Woods, Baker, & Hopper (2004)) sought to explain current practice, that is sought to provide insight into the reasons why, after adoption, some academics use technology simply for course management and efficiency, while some use it to offer enriched, often innovative, learning experiences to their students. The search was then extended beyond of the Web of Knowledge to using Google and Griffith University Library searches. The extended search yielded additional studies relating to academics blended practices, both in relation to adoption of technology and focusing on explaining how academics used the technology after adoption. The studies are synthesized in Table 1. Notable among the results was the use of technology acceptance models (Davis, 1986) as a common thread.

Consideration of the literature in table1 (note the bolded factors in the table) gives rise to some frameworks useful for beginning to understand what factors may influence how academics use technology in their teaching - technology acceptance (Davis, 1986), evolution of teaching practice (Sandholtz, Ringstaff, & Dwyer, 1997), teaching style (Grasha, 1996) and constructivist philosophy (Jonassen, 1994), and technological, pedagogical and content knowledge (Mishra & Koehler, 2006), and self-efficacy (Bandura, 1986). The frameworks provide a basis for the construction of a proposed model of factors shaping academics' use of technology in teaching. Each of the frameworks, and the emerging model factors are now discussed.

Table 1. Literature investigating factors influencing academics' technology use. Factors of interested are highlighted in bold.

Author/s	Description	Findings
Woods, Baker and Hopper (2004) Published in *Internet and Higher education*	Woods, Baker, and Hopper (2004) examined responses from academics members across 38 institutions using the Blackboard learning management system. The authors explored the factors predicting the type of usage of Blackboard whether as a supplement or for various instructional purposes such as community building, collaboration, or interactivity.	Results indicated administrative rather than integrated instructional use was more prevalent. Factors impacting the ways in which technology was used included **age, gender, nature of subject matter, academics perceptions about how students would learn best, and their personal preferences.** Academics' **experience with Blackboard** was found to be the most significant factor of usage. Academics with greater Blackboard experience tended to have more positive attitudes towards both the pedagogical potential of Blackboard and its usefulness for course administration. **Instructional experience** impacted on the academics perceptions of the benefits of Blackboard. The study was limited by the investigation of a specific learning management system and did not take into account institutional factors.
Celik (2011) Published in Ankara University, *Journal of Academics of Educational Sciences,*	Used a modified version of the Level of Technology Implementation (LoTi) Technology Use survey (Moersch, 1994). The study sought to establish the levels of technology integration in teaching strategies and the factors that hinder academics' technology integration into teaching strategies.	The study revealed most academics were not using technology effectively for instructional purposes. There was no dependency between academic qualifications and level of technology use in their teaching. Participants' level of technology integration declined with more sophisticated technologies. Among the most influential **barriers to integration of technology were found to be time and lack of professional development.**
Georgina and Olson (2008) Published in *Internet and Education* (Journal)	The study explored the impact of technology literacy and technology training on blended pedagogy use by academics. Specifically, the study addressed the impact on pedagogy of academics' self-perception of technology literacy and of training in technology literacy.	The study suggested that there is **a strong link between technology literacy and pedagogy.** It was found that small group training was more effective than large training sessions. However, the study is rather narrow in its scope. Frameworks such as the Technological, Pedagogical and Content knowledge model (Mishra & Koehler, 2006) suggest a much more complex relationship between technology and the quality of pedagogical practice when using technology than is suggested by this study.
Mehra and Mithel (2007) published in International *Journal of Education and Development using Information and Communication Technology*	Seeking to address the question of why some academics members find the idea of using technology for teaching appealing while others do not, the study investigated the perceptions of the management academics about the benefits of using technology and also considered how factors such as age, experience, time, and academic background affected the extent of use of technology for teaching.	The results of the survey of 150 respondents allowed them to be categorised into one of three groups according to technology use and perceptions. The least technology use was made by the group who **perceived technology as too complex to use and who felt intimidated by its use** in the classroom (Cynics). The second group included those who, **with the assistance of support and training, were willing to incorporate technology** (Moderates). The third group continually innovated and incorporated technology fully into their teaching (Adaptors). The study found there was no **significant relationship between: pedagogy used and the perceived usefulness of technology** (the reasons why this might be were not explored), **age and extent of technology use, academic background and extent of technology use.**

Table 1. Continued

Author/s	Description	Findings
Renzi (2008) Unpublished PhD thesis.	Used Azjen's theory of planned behaviour to explain why some academics use a learning management system in a supplemental role whilst others integrate its capabilities into their teaching model. Variables under consideration included attitude towards the learning management system, subjective norms, perceived behavioural controls, and actual behavioural control.	Results indicated that while academics have a positive attitude to the learning management system, the more significant factors in determining whether the system was used as an integrated component of teaching strategy or in a supplemental role, were **pedagogical skill along with the confidence to use technology.** The outcome of this study is indicative of the value of the Technological, Pedagogical and Content knowledge model (Mishra & Koehler, 2006)
Sturgeon (2011) Unpublished PhD thesis	The study attempted to establish factors contributing to the integration of technology with face-to-face teaching. A cross-institutional study was undertaken with 36 universities in the Appalachian Region.	**Personal use and knowledge of technology were found to be important factors in determining integration of technology.** Age was found not to be a factor although **gender appeared statistically significant,** with females reporting the use of technology for teaching more frequently than males. The study suggested that the most **important factor determining use of technology was "the knowledge that doing so would enhance student learning**"(p.v)
Thornton (2008) Published in *Proceedings of ASCILITE conference* 2008	Used the idea of 'cognitive frames' and 'sense making' to explore 'how [university] teachers deal with their encounters with courseware' (Thornton, 2008, p. 1040). The study highlighted how teachers' pre-existing ideas about teaching and technology came into play when they produced their learning designs.	**Technological expertise was much less important than "a strong sense of epistemic purpose**" (Thornton, 2008, p. 1040) in producing effective learning designs. Effective teaching resulted when the task of combining face-to-face teaching with technology was framed as a pedagogical problem, rather than as a media problem. Findings of Thornton's study are consistent with findings of literature related to professional development such as Salter (2006), and Keengwe, Georgina and Wachira (2010) who found linking the learning of technical skills with pedagogy was important to facilitate academics' use of technology for pedagogical purposes.

FRAMEWORKS AND EMERGENT FACTORS

Technology Acceptance

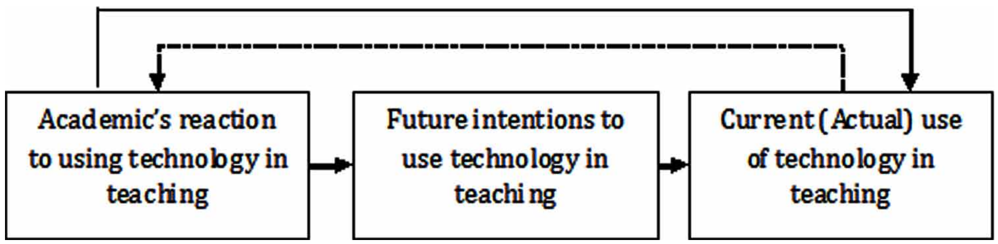
The core concept underlying technology acceptance models (Davis, 1986; Venkatesh & Bala, 2008; Venkatesh & Davis, 2000; Venkatesh, Morris, Davis, & Davis, 2003) is that individuals' reaction to using information technology and their actual use of technology influence each other. Furthermore, individuals' reactions to using technology influence future intentions, which in turn influence the actual use of technology. Venkatesh et al. (2003, p. 427). The core concept of technology acceptance models can be adapted, as shown in figure 2, to underpin a model of factors influencing how academics, after adoption, use technology.

In addition to the foundation in figure 2, other constructs from technology acceptance potentially contribute towards a model of factors that influence how academics' use technology in their teaching. These constructs are: Normative influences, perceived ease of use, perceived usefulness, perceived feasibility. Each of these is discussed below from the context of academics' use of technology in teaching.

Normative Influences

Normative influences refer to an individual's belief about whether or not people important to them think the behavior should or should not be enacted (Fishbein & Ajzen, 1975). It would be reasonable to assume that the opinions of supervisors and peers are important influences

Figure 2. The core constructs of technology acceptance models as they apply to academics' use of technology in teaching adapted from (Venkatesh, Morris, Davis, & Davis, 2003, p. 427)



on academics' practices. Examining some of the literature related to professional support shows this to be a reasonable expectation. For example, in a paper reporting on the implementation of online assessment as an institutional strategy at the University of Glamorgan (Chew, Jones, & Blackey, 2010), it was found that having senior university staff members using blended strategies had a generally positive influence on the uptake of technology-infused strategies by more junior academics members. According to Chew, Jones, and Blackey (2010), the influential role of peers became obvious when certain academics members who were using blended practices were publicly cast in the role of 'champions' within each academic area, and lead to positive influence on the uptake of technology-infused strategies by academics members.

The influence of peers and supervisors aside, it is possible that students' opinions also have the potential to influence academics' use of technology. Compelling evidence for this argument is found in the volume of literature concerned with the student opinions of using technology in teaching (Mitchell & Forer, 2010; Salmonson & Lantz, 2005; Richardson & Turner, 2000). Against this background, it is proposed that normative influences are an important factor to consider when seeking understanding of why academics' use technology as they do in their teaching.

Perceived Ease of Use

In the present study, 'perceived ease of use' refers to the amount of effort an academic believes he or she needs to expend to implement teaching strategies that require the use of both technology and face-to-face teaching. Research on academics' acceptance of technology has often found perceived ease of use to be a determinant of technology acceptance (e.g. Ahmad, Madarsha, Zainuddin, Imsail, & Nordin, 2010; Halawi & McCarthy, 2000; Kripanont & Tatnall,2009). Conceivably, perceived ease of use is a factor with the potential to impact on how academics use technology in teaching, as demonstrated by Mehra and Mithel (2007).

Perceived Usefulness

In the context of the present chapter, perceived usefulness is the degree to which academics believe that using technology together with face-to-face teaching strategies will enhance teaching effectiveness. In existing research about technology acceptance among academics, perceived usefulness is consistently found to be a significant determinant of whether or not an academic will use technology in teaching (Halawi & McCarthy, 2010; Chang et al., 2011, Tarcan, Varol, & Toker, 2010). Some studies (Sturgeon, 2011; Thornton, 2008; Woods, Baker, & Hopper, 2004) (Table1) have also shown that perceived usefulness also plays a significant role in *how* the technology is used after adoption.

Perceived Feasibility

Given that implementing technology-infused teaching approaches generally requires a significant investment of time and resources, it is likely that academics' perceptions of feasibility conditions such as time, funding, support, and infrastructure play a role in shaping the extent to which technology is used by academics in their teaching. Indeed Celik (2011) found time and lack of professional development to be major barriers for academics seeking to integrate technology with teaching. Furthermore, feasibility conditions such as time, infrastructure, professional support, technical support, and funding have been identified as factors determining technology acceptance in existing studies such as those by Bagher, Marek, and Sibbald (2007), Davis and Fill (2007), Kistow (2009), Ocak (2010), Stewart, Bachman, and Johnson (2010), and Wang (2009).

Evolution of Teaching Practice

The technology acceptance framework aside, a consideration of literature, especially Woods, Baker, and Hopper (2004), and Mehra and Mithel (2007), points to evolution of practice and the factor of experience as also useful to understanding academics' use of technology. Evidence of stages of evolution in the use of technology for teaching (as a result of experience) has been observed by a number of authors including Goddard (2002), Sandholtz, Ringstaff, and Dwyer (1997), and Toledo (2005). The number and name of stages identified varies with different authors. Sandholtz, Ringstaff, and Dwyer's (1997) five stages best capture the essence of the idea of evolution of stages. The first stage, termed 'entry point' by Sandholtz, Ringstaff, and Dwyer (1997) begins with awareness of the existence of technology for teaching though it is not used in teaching. In the second stage, the adoption stage, technology is used in the teaching context but primarily for increasing efficiency. In the third stage, there is some limited use of technology in learning strategies, usually for supplemental reasons and has minimal impact of practice. In the fourth and fifth stages, appropriation and invention, technology is progressively embedded in learning strategies to a greater extent and leads to transformation of practice.

The idea of evolution of practice is not dissociate from ideas presented in technology acceptance models. Evolution of practice relates to experience and the effect of those experiences. The technology acceptance models (Venkatesh & Bala, 2008; Venkatesh & Davis, 2000; Venkatesh, Morris, Davis, & Davis, 2003) include experience as influencing constructs such as perceived ease of use, perceived usefulness and behavioural intent.

Teaching Approach and Constructivist Philosophy

It is worth noting that Woods, Baker and Hopper (2004) found academic perceptions about how students learn best influenced how academics used technology in their teaching. It is now argued that teaching approach should feature in a model of factors influencing how academics use technology in their teaching.

Aligned with Grasha's (1996) conception of teaching approach is used here refer to the characteristic manner in which individual teachers design the instructional process. It follows that when technology is used as part of the instructional process, teaching style will have bearing on how the technology will be used (Zisow, 2000; Weitkamp, 2006).

Individual beliefs about how students learn best are embedded in the idea of teaching approach. Some prior research has shown that constructivist teaching approaches seem to be conducive to using technology as an intrinsic part of learning activities (Judson, 2006; Grasha, 1996; Weitkamp, 2006).

Some literature suggests that those with teaching approaches more aligned with constructivist ideals are more likely to exploit new technologies to design active, student-centered, learning that encourages active knowledge building (Jonassen, 1994; Kramer & Schmidt, 2001; Strommen, 1999) and thus achieve learning related objectives (Judson, 2006), rather than use technology for administrative or supplemental purposes only. For example, Preston, Phillips, Gosper, McNeill, Woo and Green (2010) used Trigwell and Prosser's (2004) *Approaches to Teaching Inventory* to profile teachers and found that those teachers who viewed the main goal of teaching as simply delivery of content were likely to consider Web based technologies not useful for learning and therefore did not use technologies for learning activities. However, Palak and Walls (2006, p. 436) point out that "teachers' beliefs and practices are context bound" and thus belief in constructive ideals alone does not necessarily result in student-centered use of technology. Supporting this argument, Florini (1989) maintains that the personal models teachers' use for determining appropriate technology use is the result of interplay between awareness of personal teaching style, understanding of the characteristics of the media, and the context of use.

Technology, Pedagogy, and Content Knowledge Framework

Congruent with the idea that teachers' use of technology is not the result of a single or simple characteristic such as teaching style, Mishra and Koehler (2006) assert that how teachers use technology for teaching is determined by a "complex interplay" (p.1025) among three bodies of knowledge: pedagogy, technology, and content. Mishra and Koehler (2006) maintain that teachers must possess technical knowledge and pedagogical knowledge as well as content knowledge as a pre-condition for the design and use of effective strategies for using technology to achieve learning objectives. For example, teachers with good content knowledge and good pedagogical knowledge do not necessarily have the skills required to effectively use technology to create learning activities that support curriculum objectives (Thornton, 2008).

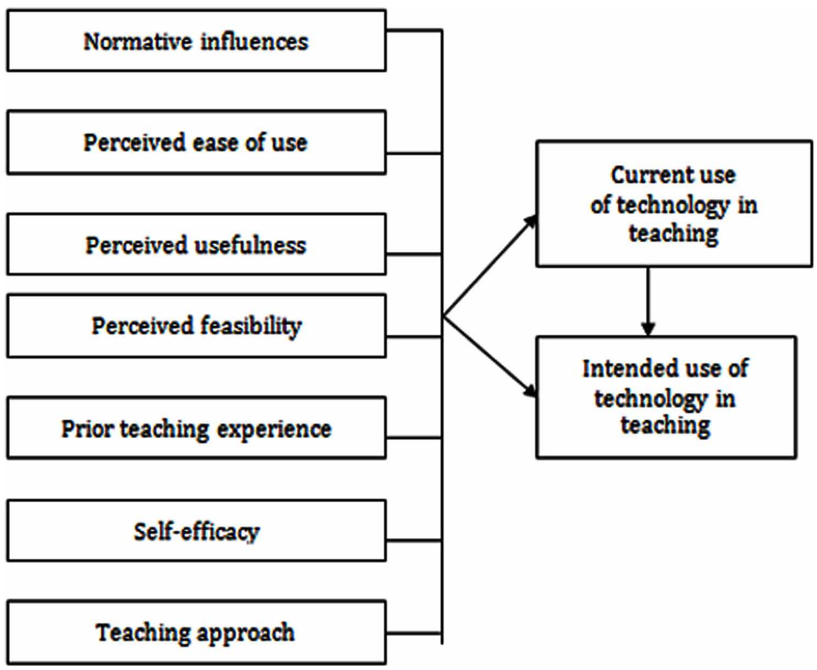
Self-Efficacy

Self-efficacy is the final construct proposed for a model of factors influencing how academics use technology. Mehra and Mithel (2007), and Renzi (2008) both identify confidence to use technology as an important factor determining how academics used the technology. The concept of confidence is encapsulated in the idea of self-efficacy (Bandura, 1986) and is defined as the belief in one's capacity to achieve an undertaking. An interesting extension is the framing of self-efficacy using the technology, pedagogy, and content knowledge framework (Mishra & Koehler, 2006) as done by Nathan (2009) and Albion, Jamieson-Proctor and Finger (2010) to explore primary teachers' use of technologies in the classroom.

When self-efficacy is framed by Mishra and Koehler's framework, it refers to academics' (as teachers) beliefs about their ability to (or confidence to):

- Use technology (technical knowledge);
- Design effective teaching strategies (pedagogical knowledge);
- Understand course content (content knowledge);
- Make good decisions about teaching approaches appropriate to teaching the content (pedagogical-content knowledge);
- Identify which technologies can be used in the content area (technological-content knowledge);
- Understand the attributes of the technology and how they can be used to form new teaching strategies (pedagogical-technological knowledge);
- Identify the attributes of technology as well as design new strategies using those attributes to best teach the required content knowledge (technological-pedagogical-content knowledge).

Figure 3. A proposed model of factors influencing how academics' use technology in teaching



A PROPOSED THEORETICAL MODEL OF THE ACADEMICS' USE OF TECHNOLOGY IN TEACHING

Bringing together the underlying frameworks and the constructs discussed above leads to the proposed theoretical model of academics' use of technology in teaching (figure 3)

The core constructs of the technology acceptance models underpin the model (Figure 2) shown in Figure 3. The proposed model suggests that normative influences, perceived ease of use, perceived usefulness, perceived feasibility, prior teaching experience, self-efficacy and teaching approach are likely to be factors important to how academics' are currently using technology in their teaching and to how they intend to use it in the future. The experiences of current use of technology will also feed into future intentions of use.

FUTURE TRENDS

The pressures on higher education due to globalization and the changing nature of student needs are not likely to relent in the near future; and it is envisaged technology will continue to be a crucial element of higher education teaching contexts. Add to the mix the rapidly changing nature of technology and it is evident that there is an urgent need to support academics such that their use of technology provides not only efficient, but also highly effective learning experiences for students. Research into understanding what shapes how academics use technology in their teaching must inform the design of professional support strategies. Well-informed support strategies are more likely to succeed in changing academic practice.

Although the proposed theoretical model may be seen as oversimplifying what is undoubtedly a complex interaction of many factors, the model provides a firm basis for the much-needed research seeking to understand the factors that shape how academics will use technology in their teaching.

CONCLUSION

This chapter has identified the effective use of technology in higher education to be an important issue for institutions given the competitive climate of globalization, and the demands of technology savvy cohorts of students. It has been argued that, after adoption of technology in their teaching, academics oftentimes do not exploit it for increasing pedagogical effectiveness – and the widespread adoption of effective teaching practices is, alongside effectiveness and efficiency, critical if universities are to maintain competitive advantage in the current climate. It was also argued that understanding the factors that shape how academics use technology in their teaching provides a valuable insight into how to best support academics such that they are able to use technology to achieve more effective teaching practices. This chapter sought to identify potential key factors influencing academics current and future practices in using technology in teaching. A model was proposed that offers some direction for further investigation into influences shaping academics' technology-infused teaching practices.

KEY TERMS AND DEFINITIONS

Constructivist Philosophy: A set of beliefs about teaching and learning in which the learner is viewed as an active participant in their own knowledge building process, and the teacher as a facilitator of that active knowledge building process.

Normative Influences: The views expressed by people viewed as important by an individual can affect the actions of the individual.

Perceived Ease of Use: The amount of effort an individual believes he or she needs to expend to implement something.

Perceived Feasibility: The extent to which an individual believes that they have the required resources (or skills) to successfully undertake the task.

Perceived Usefulness: The extent to which an individual believes that undertaking a particular task will result in a positive gain.

Self-Efficacy: The extent to which an individual believes in their own ability to undertake a task and successfully complete it.

Teaching Approach: Refers to the manner in which different teachers design of instructional strategies in different ways as a result of their individual pedagogical beliefs, preferences and attitudes.

Technology-Infused Teaching: Using technology in teaching for pedagogical reasons (rather than only efficiency and flexibility). Technology infused teaching uses technology rich teaching strategies together with face-to-face teaching to achieve substantial learning objectives.

Chapter 12
A Mobile Learning Overview by Timeline and Mind Map

David Parsons
Massey University, New Zealand

ABSTRACT

Mobile learning has been a research topic for some 20 years. Over that time it has encompassed a wide range of concepts, theories, designs, experiments and evaluations. With increasing interest in mobile learning from researchers and practitioners, an accessible overview of this area of research that encapsulates its many facets and features can provide a useful snapshot of the field to interested parties. This article provides a summary of the field of mobile learning, applying the main analysis categories of research, technology, content, learning and learner. The author presents these categories and subcategories in the form of a mind map, which outlines the details of the major themes in mobile learning. In addition, the author contextualises the key developments in mobile learning in a timeline. The intent of this article is that it may serve as an introduction to the research field of mobile learning, enabling researchers to quickly familiarise themselves with the type of work that has been done in the past, and the potential areas of investigation that might prove fruitful in the future.

INTRODUCTION

Mobile learning is an increasingly popular approach to learning with technology, particularly with the increase in BYOD (Bring Your Own Device) approaches to classroom learning, where students are using their own mobile devices to learn. With this increasing interest in the subject, it may be a useful aid to new researchers, or other interested readers, to provide an accessible overview of mobile learning that encompasses its many facets and features. Although there have been many reviews of the mobile learning literature, these have tended to focus mostly on the nature of the work from a research perspective. Further, they have focused on a specific subset of the overall literature. For example Wingkvist & Ericsson (2011) surveyed the papers published in the Mobile and Contextual Learning (mLearn) conference series, but classified them according to only two dimensions: research method and research purpose. Pollara & Broussard (2011) provided a review focused specifically on student learning outcomes and processes. Sattler et al

DOI: 10.4018/978-1-4666-8246-7.ch012

(2010) focused on the benefits (particularly to constructivist learning) and challenges (buy-in, interface issues, cost and infrastructure.) Orr (2010) focused on pedagogy and constraints. Some review articles have specifically confined themselves to a particular type of mobile learning, for example mobile language learning (Viberg & Grönlund, 2013.) It is, of course, in the nature of a comprehensive literature review that it will sacrifice breadth in favour of depth, within a chosen area of investigation. The intention of this article is to sacrifice depth in favour of breadth, in order to provide a full-landscape view of the field of mobile learning, which has so far been lacking from the literature.

THE CONCERNS OF MOBILE LEARNING RESEARCH

A number of authors have attempted to break down the field of mobile learning research into various specific concerns. The ways in which this has been done has, of course, varied depending on the focus of interest of these authors. From a general perspective, for example, Traxler (2009) defined a number of mobile learning categories: technology-driven, portable, connected classroom, informal, personalized, situated, performance support and in the development context. He also outlined some aspects of affordances; infrastructure, sparsity, policy agenda and blended learning modes. Laurillard (2007) provided a slightly different interpretation, pointing to aspects of mobile learning's uniqueness as a learning mode by referencing learner generated contexts, digital objects co-located with the learner, the three 'mobilities' in m-learning (learners, technology objects, and information) and motivation through ownership and agency. While these categories are all relevant and helpful, this article attempts to develop a new overview, based on a broad analysis of the literature up to and including 2013, and provide visualisations of the main themes, concepts and concerns of mobile learning.

ANALYSIS METHODOLOGY

The methodology used in this article was based on seeking comprehensive coverage of mobile learning research as represented primarily by journal articles and book chapters, and presenting visualisations of our findings (in the form of a timeline and a mind map.) Our main sources were journal articles on the topic of mobile learning revealed in a search of the Web of Science (400 articles), all articles published in the International Journal of Mobile and Blended Learning (94 articles), chapters in mobile learning books (~50), and additional articles found in a search of Google Scholar that covered concepts not previously identified, and included additional types of publication such as conference papers (~50). Each paper was analysed in terms of its own statements of its key features and contribution, based mainly on the abstracts and conclusions of the papers, and visualisations of the data were developed incrementally as new concepts were added, revised and rearranged. In seeking a saturated sample, these data were accumulated until the additional concepts being gleaned from the literature were either (a) already included in the data or (b) were only providing further examples that were indicative rather than exhaustive. For example, one of our themes related to the subject content of mobile learning systems. Since the number of subjects became increasingly large, the final visualisation only includes a small subset of the most popular subjects covered. The papers cited in the commentary provide indicative examples of each of the main concepts of the mind map, though in many cases there were many other papers that could equally have represented the chosen concepts, and it is not claimed that each of these examples is the 'best' paper that could have represented each individual concept. Further, due to limitations on space, it has not been possible to provide commentary and references for every single concept in the mind map, so the article focuses instead on what is hoped to be a representative sample.

Data Presentation

This article presents its landscape view of the field of mobile learning in the form of a timeline (mapping in time) and a mind map (mapping in space). Timelines are an important tool in the visualisation of temporal data, for example they have proved particularly useful in the visualisation of time-sensitive medical data (e.g. Bui, Aberle & Kangarloo, 2007). In this article, the value of temporal visualisation is to give greater clarity to what we have identified as key phases in the evolution of mobile learning research.

Whilst timelines are well established as having value in several research domains, the use of mind maps is perhaps more controversial. Although this approach to visualization is relatively subjective, it is a qualitative approach that allowed us to find creative associations between ideas, as opposed to some other approaches that simply present quantitative data (Davies, 2011). It enabled the researchers to work creatively and interactively to integrate large volumes of individually captured data. Although the current work does not address this aspect, it also potentially supports additional services such as certain types of information search (Beel & Gipp, 2010). Through an iterative process of refinement, we have applied the main analysis categories of research, content, technology, learning and learner, with a range of subcategories and representative exemplars. There is a large number of Mind Map creation software tools available, but the mind map presented here was created using XMind (http://www.xmind.net/).

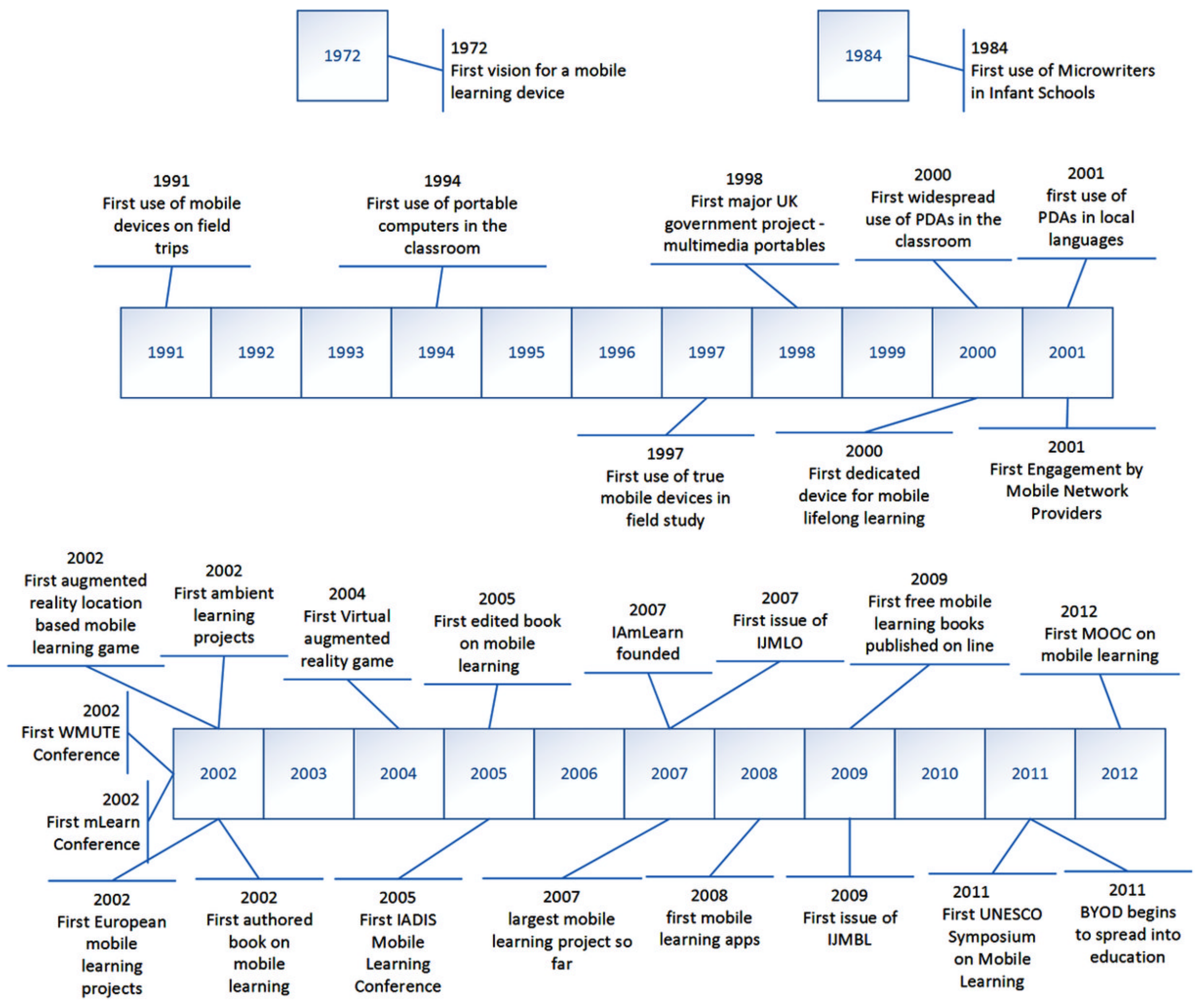
A MOBILE LEARNING TIMELINE

The mobile learning timeline (Figure 1) describes the evolution of mobile learning through a series of significant 'firsts'. The events on the timeline are of various kinds; notable research projects, the establishment of relevant journals and conference series, and some technology related innovations. In each case, an attempt has been made to identify the first occurrence of each type of mobile learning project, forum or application. This has two main purposes. First, it allows the reader to see the roots of mobile learning research, and to appreciate its history. Second, it reveals some important themes in the field that are explored in more detail in the mind map described later in this article. The timeline was partially crowdsourced by seeking contributions and debate among members of the International Association for Mobile Learning via their shared mailing list.

The first two items on the timeline are separated by several years from the main body of activity. The first of these is Alan Kay's visionary Dynabook, a vision for future mobile learning, which laid out many of the affordances for a mobile learning device that we now take for granted (Kay, 1972.) However, it was many years before anything like Kay's vision could be realised in a practical way. The first attempt to use a small device for learning seems to be the use of Microwriters in Infant Schools (High & Fox, 1984). Of course these simple word processing devices were very primitive compared to the concept of the Dynabook, and classifying them as mobile learning might be stretching a point. Nevertheless they were small semi-portable devices used to encourage autonomous and collaborative learning, so that within the technical limitations of the devices, this project was pioneering in some of the concepts that were to prove central to mobile learning.

The first attempt to take mobile learning out of the classroom, to make it truly mobile, appears to have been the Apple Classrooms of Tomorrow (ACOT) project in 1991, including the first use of mobile devices for field trips (Grant,1993), which has since become a core context for mobile learning. 1993 saw the Pupils' Learning and Access to Information Technology (PLAIT) project, which was probably the first project to use truly portable (though not really mobile) computers in the classroom (Gardner et al., 1994.) If nothing else, this project first raised the seemingly end-

Figure 1. A Timeline of mobile learning research



less debates about how mobile learning might or might not impact on learning performance and learner attitude. While early field-based projects used devices that might be better described as portable rather than mobile, the first project to use truly mobile devices for learning in the field was probably the Cornell Plantations projects in 1997, which utilised the (then new) Windows mobile devices (Rieger & Gay, 1997.) At around the same time, the indoor equivalent of the field trip, the museum or gallery tour, was also a focus of innovative mobile projects, including Hyper-interaction within Physical spaces (Oppermann & Specht, 1998.)

While previous projects has been either small scale or driven by vendors, the first large scale government funded project was the 1998 Becta Project in the UK, Multimedia Portables for Teachers. Although this focused more on the portable than the mobile, it was significant in its emphasis on educators rather than learners, and on the use of multimedia and internet connectivity to support teaching and learning (Harrison et al, 1998.)

The first attempt to truly address Kay's vision of a mobile learning device was probably the HandLeR Project in 2000, which sought to design and build a mobile device that would directly support mobile learning (Sharples, 2000.) Around the same time, Palm were distributing the Palm Education Pioneer grants, to provide handheld computers for teachers and their students in K-12 classrooms. This may be seen as the first project designed to see large scale use of mobile devices by children for learning within the classroom. Perhaps less high profile, but also significant, the Enlace project provided the first use of Personal Digital Assistants for mobile learning in languages other than English (Rodríguez et al, 2001)

While manufacturers of mobile devices (Apple, Microsoft, Palm) had been active in promoting and supporting mobile learning initiatives, mobile network providers finally became formally involved in 2001, with the inaugural meeting of the European m-learning Forum (PJB Associates, 2001.) This signalled the increasing move away from standalone mobile learning tools deployed on disconnected PDAs to connected tools, utilising the content and collaboration opportunities of wireless mobile devices.

2002 was a very significant year in the development of mobile learning. As technology developed, more ambitious forms of mobile learning became possible with ambient, pervasive and ubiquitous technologies. Perhaps the pioneers of this type of mobile learning were the related Hunting of the Snark and Ambient Wood projects, explorations in contextual learning through ambient devices that pushed the boundaries of mobile learning in outdoor environments (Price et al., 2003, Harris et al, 2004). In a similar vein, the first augmented reality location based mobile learning game, Environmental detectives, was developed (Klopfer, Squire & Jenkins, 2002.)

The first authored book on mobile learning appeared in 2002, and interestingly was based not on classroom learning but on work-based learning, reflecting a quick uptake in the United States of mobile technology by employers who saw the potential for mobile learning in a work-based training context (Gayeski, 2002). 2002 also saw the beginning of the first major mobile learning projects to be supported by European funding. The M-Learning Project was funded by the European Fifth Framework programme to help disaffected learners aged 16 to 24, while the more ambitious Mobilearn Project was a worldwide European-led project exploring context-sensitive approaches to informal, problem-based and workplace learning. Further major events in 2002 were the first meetings of two conference series that have continued to act as significant forums for the research community. The First IEEE International Workshop on Wireless and Mobile Technologies in Education (WMTE) took place at Växjö University in Sweden, while the first World Conference on Mobile and Contextual Learning (mLearn) was held at the University of Birmingham, UK, though it was initially called the European Workshop on Mobile and Contextual Learning. mLearn is the longest continuously running international conference series on mobile learning. A further conference 'first' took place in 2005, with the IADIS Mobile Learning conference series being inaugurated in Malta. This conference series differed from its predecessors in that it remains focused on European venues.

2005 also saw the publication of the first edited book on mobile learning (Kukulska-Hulme & Traxler, 2005.) The Advanced Mobile and Ubiquitous Learning Environments for Teachers and Students (AMULETS) project in 2006 might also be seen as innovative in its blending of mobile device use in the field with integral classroom activities, bringing together the two contexts of mobile learning (in the classroom or in the field) that had been previously explored separately. Another evolutionary step from 2006 was Futurelab's Savannah project, which was the first mobile learning application that overlaid imaginary (rather an informational) virtual content onto real world contexts (Facer et al. 2004).

2007 saw the beginning of the large scale MoLeNET (Mobile Learning Network) Project in the UK, which claimed to be the world's largest and most diverse implementation of mobile learning to date, including 50,000 learners and 4,000 staff. The increasing maturity of mobile learning as a research field began to lead to more formal outlets for publication and collaboration. The first issue of the International Journal of Mobile Learning and Organisation, the first journal to include mobile learning in its title, was published in 2007. This was followed in 2009 by the first issue of the International Journal of Mobile and Blended Learning. The International Association for Mobile Learning (IAMLearn) was established in 2007, while in 2009 the first free mobile learning books were published on line (Ally, 2009; Herrington et al., 2009.) Meanwhile, technology development continued apace. In 2008 the first mobile learning apps began to appear in the App stores for both Apple and Android devices, enabling mobile learning apps to be distributed for both platforms.

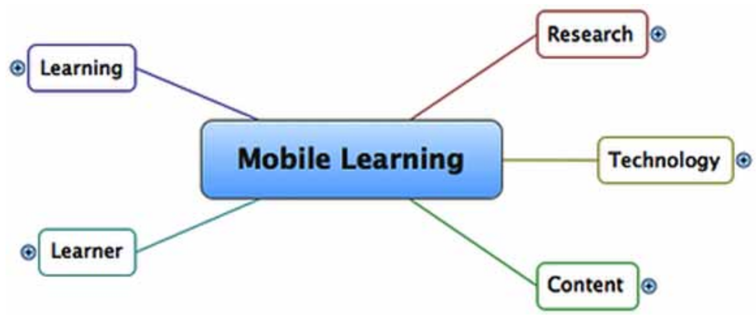
Another significant first took place in 2011, with the first UNESCO Symposium on Mobile Learning, acknowledging that mobile learning was by now of global interest, and a potentially important tool for educational delivery in developing nations. The following year, with increasing interest in the potential of massive open online courses (MOOCs), the first MOOC on mobile learning (MobiMOOC) was delivered. Around the same time, a sea-change began to occur in the way that mobile learning was deployed in schools and higher education institutions, with the increasing uptake of bring your own device (BYOD) policies (Norris & Soloway, 2011.) This change suddenly brought mobile learning into the mainstream, challenging mobile learning researchers to adapt to the new world of research challenges and opportunities brought by mass adoption of mobile learning.

It is notable that the timeline reveals three distinct phases in mobile learning evolution. Initially, innovation is driven by individual researchers or small groups, perhaps supported by technology vendors such as Palm and Apple, exploring new concepts in teaching and learning by being early adopters of new technology. Later, we see a series of large scale projects, sponsored not by commercial enterprises but by quasi-governmental organisations such as the European Union. More recently, we see new channels of dissemination and collaboration; journals, conferences, MOOCs etc. Underlying these developments we see the evolution of mobile technology from early portable devices, through PDAs, to contemporary touch screen smart devices, owned by learners. Given this context, it may be useful to the researcher to consider what the next phase of mobile learning research might be, and how the research community might contribute to future developments.

A MIND MAP OF MOBILE LEARNING

In creating our mind map, the main areas we have identified are: Research, Technology, Content, Learning and Learner (Figure 2). These concepts 'bubbled up' through the process of interactively developing the mind map, so were not starting points in our analysis, rather they were the final result of generalising concepts from the specific to the generic. In the remainder of this article we have attempted to summarise the key concerns of each area, presenting the relevant subtree of the mind map, with some indicative examples where appropriate. For example under 'Content', one of our subconcepts is 'subject specific (content)'. Within this branch of the mind map we include a number of popular subjects that have been addressed by mobile learning, but this is by no means an exhaustive list. Similarly under the 'Learning' concept, in the 'Specific Context' subconcept, we include some popular contexts for mobile learning. Again, these are only intended to be indicative. A similar philosophy applies to most of the branches of the mind map.

Figure 2. A mind map of mobile learning categories



RESEARCH

Figure 3 shows the subtree from the mind map that explores the overarching theme of 'Research'. Mobile learning research has fallen into a number of categories. Some papers have focused on theory, with activity theory being one of the most popular theories applied to mobile learning (Uden, 2007). However there are many other theories that have been found relevant, including psychological theory (Brown & Campione, 1996), in particular behavioural psychology, flow experience (Csíkszentmihályi, 1996; Park, Parsons & Ryu, 2010) social constructivism (Cochrane & Bateman, 2010) and constructionism (Patten et al., 2006). Learning theories that stress context, a particularly important feature of mobile learning, include situated cognition (Brown, Collins & Duguid, 1989) and distributed cognition (Hutchins, 1995). Siemens (2004) also stresses the importance of context in applying connectivism to mobile learning. There have also been efforts directed at creating an overarching theory for mobile learning research (Sharples, Taylor & Vavoula, 2007). Theories that apply specifically to practical aspects of education are clearly important in mobile learning, for example experiential learning (e.g. Facer et al., 2004)

A large number of methods have been used in mobile learning research. A popular strand of research is the review paper, several of which have been mentioned in the introduction. However most research addresses new areas of investigation, many of which involve human subjects, since the main purpose of mobile learning research is to measure its effects on how people learn.

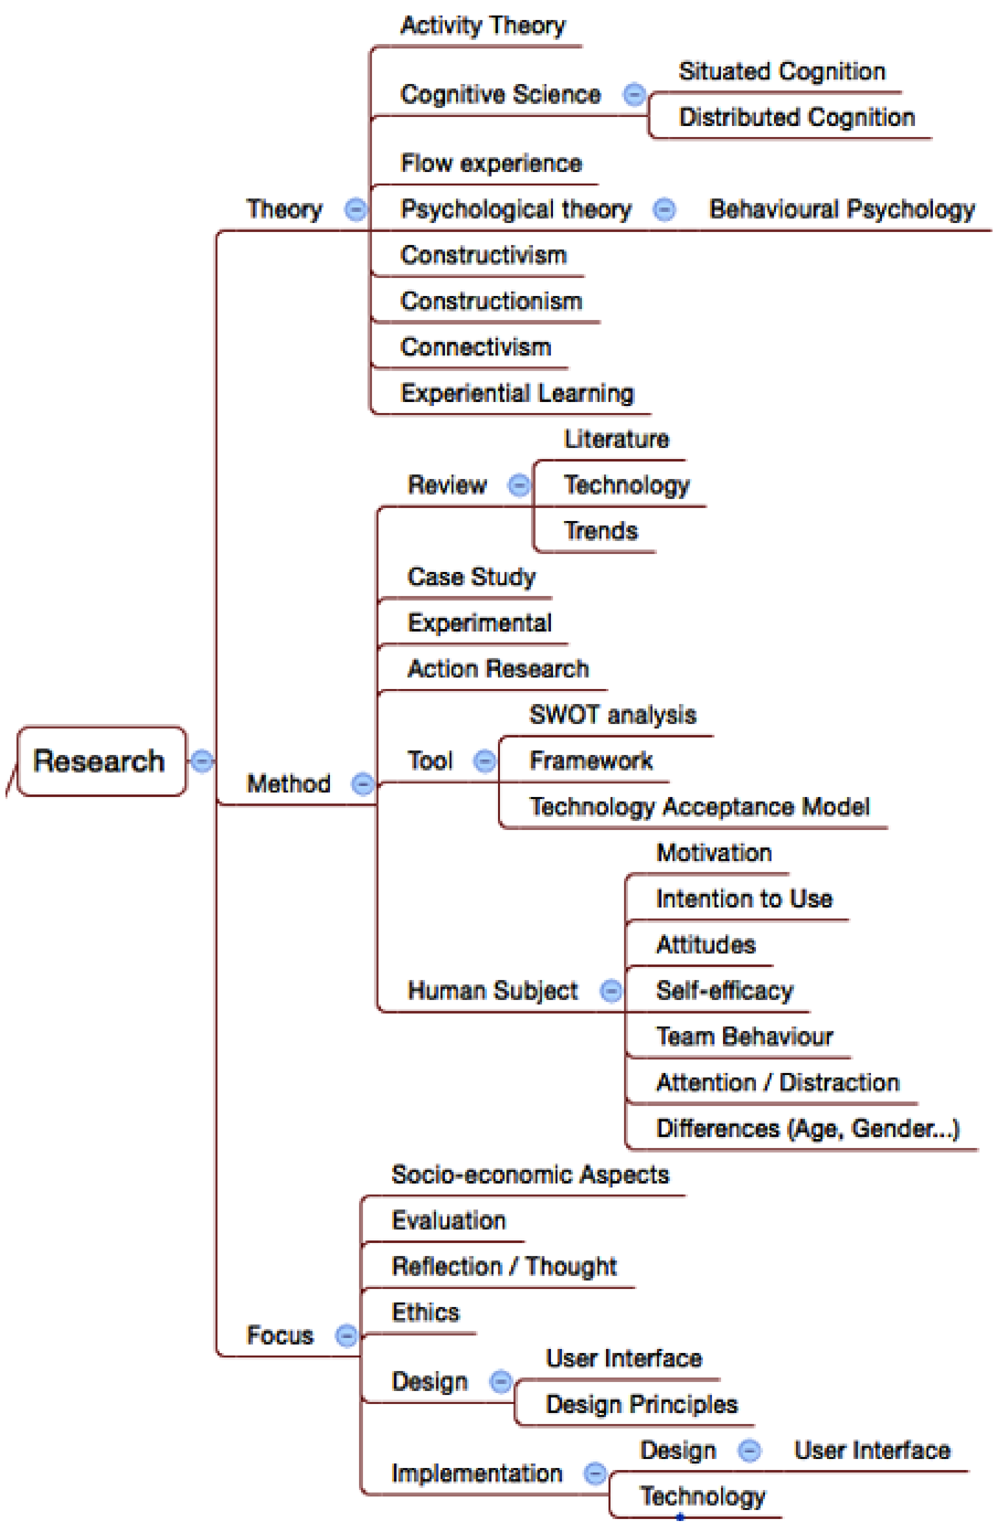
The focus of research may range from general thought pieces on the philosophy of mobile learning to specific implementations of hardware or software tools. All research needs some form of evaluation, and a number of authors have tried to address how mobile learning interventions should be evaluated, including Traxler & Kukulska-Hulme (2005), Motiwalla (2007) and Vavoula & Sharples (2009).

Research into design has been approached both from the general perspective of design guidelines and frameworks (Parsons, Ryu & Cranshaw, 2007), in specific areas of design concern such as the user interface (Carmen et al., 2012) and also looking at the design (and implementation) of individual mobile learning applications (Sharples, Corlett & Westmancott, 2002.) While not all research into design formally uses design based research as a methodology, there are a number of examples that do (e.g. Ahmed, & Parsons, 2013).

TECHNOLOGY

Figure 4 shows the subtree from the Mind Map that explores the overarching theme of 'Technology'. This theme is divided into technology platform concerns (devices and communications) as well

Figure 3. The 'Research' branch of the Mind Map



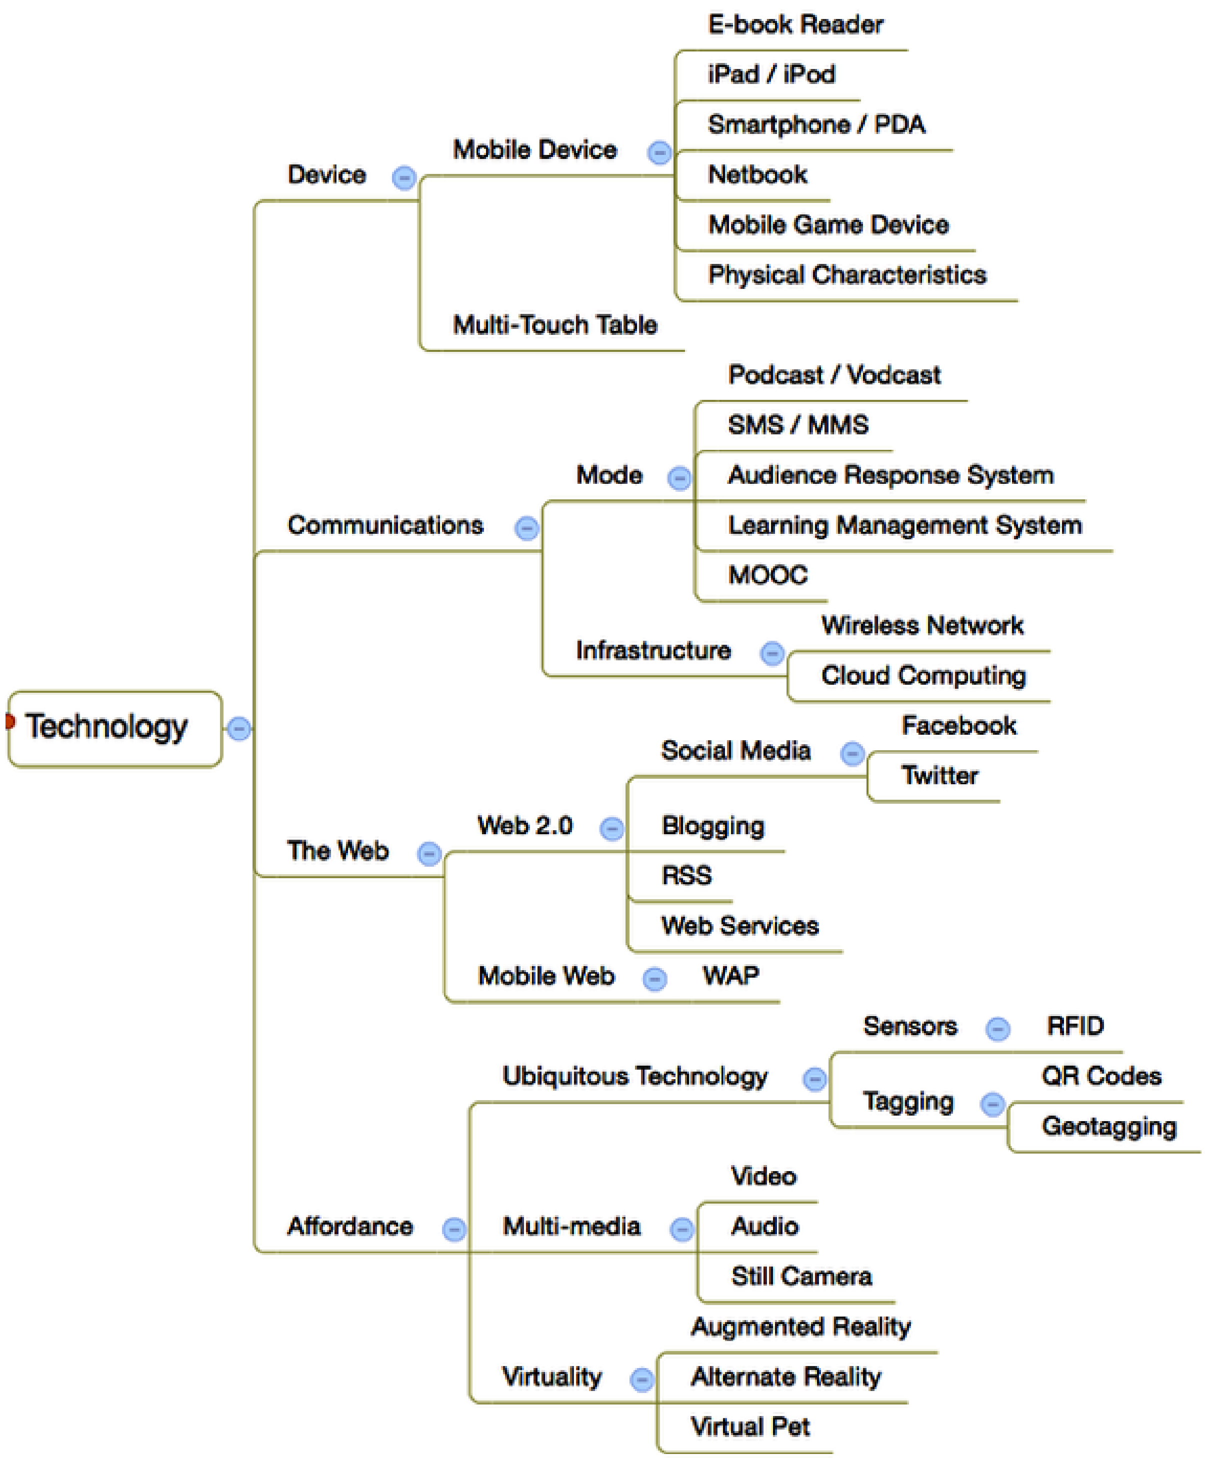
as potential ways of using these technologies (web-based applications and system affordances). One aspect of mobile learning that is difficult to ignore is the device, since the rate of change of these technologies is such that it constantly drives new research opportunities. While the device itself is not the subject of the research, specific devices inevitably get used in empirical research projects. Thus mobile learning has, over the years, used many different types of technology, for example iPods, MP3 Players, Personal Digital Assistants, USB Drives, E-Readers, Smart Phones, UMPCs, Laptops and Tablet PCs (Corbeil, 2007). In some cases, specific mobile technologies have been chosen because they are particularly useful in a given context. A good example of this is the E-Reader, which can provide large volumes of material when offline. For example Havelka (2011) described the use of E-Readers with nursing faculty and students, because these users require instant access to large amounts of reference material that would be inefficient to download on demand. E-Readers have also been used in a prison context to support mobile learning where internet access is forbidden (Murphy, Bedford, & Farley, 2014). While many studies focus on particular technology, others compare different technologies, for example Martin & Ertzberger (2013) compare iPods, iPads and traditional computer based instruction.

Along with the devices themselves, technologies for communications have also evolved considerably, changing the focus of research. Many early mobile learning systems relied on SMS text messaging (Bollen et al. 2004), and indeed this simple technology still has a role to play in mobile learning systems in parts of the world where mobile device ownership is predominantly focused on low-end devices rather than smart phones or tablets (e.g. Cavus & Ibrahim, 2008.) Similarly, with the rise of personal digital audio devices, podcasting became very popular (Read, 2005), followed by vodcasting, as more devices became capable of playing video (Edwards, Jones, & Murphy, 2007.) Not all of this work was confined to one way broadcasting. Some mobile learning using small video capable devices enables the learners to develop and share their own content (Wilson, Andrews, & Dale, 2009.) Thus when we refer to communication, we are concerned not only with the technologies that support it, but the modes of communication that leverage this infrastructure, such as audience response systems and learning management systems.

A consequence of increasing access to communications technology has been the increasing use of web based tools. Indeed, in the first decade of the 21st century, the concepts of content creation and sharing became increasingly prevalent as Web 2.0 tools became commonly used as a means of supporting mobile learning where both teachers and learners could create and share content, using various features of Web 2.0 technologies such as blogging (Pierroux, Krange & Sem, 2011) and social networking (Pimmer et al, 2012.) The affordances of these web 2.0 tools enabled educators to support constructivist learning in their courses (Cochrane & Bateman, 2010.) As the technology continues to evolve, mobile learning researchers embrace these changes, for example the rapid adoption of tablet computers (Melhuish & Falloon, 2010) and cloud computing (Verma, Dubey & Rizvi, 2012.)

Technological advances have increased the affordances of mobile learning. These range from the straightforward concepts of multimedia, to more complex types of affordances such as ubiquitous technologies and virtuality. There are a number of examples of work where some kind of virtuality is introduced into the mobile learning process. This includes augmented reality (Price & Rogers, 2004), mixed reality, where real and virtual worlds are combined in real time (Doswell & Harmeyer, 2007) and alternate reality. Alternate reality activities are a combination of searching for information and sharing information, but have no predefined narrative. Open ended alternate reality is uncommon in learning activities, as they tend to be more structured. However there are some

Figure 4. The 'Technology' branch of the Mind Map



interesting hybrids of mixed and alternate reality, where the investigation is loosely structured. Kocher, Rusnak & Eklund (2010) emphasise a ludic (playful) approach focused on storymaking, which embodies ambiguous properties giving implicit direction for participants to collaborate with each other and understand what they can or should do. A broader and longer running alternate reality game that included elements of mobile device creativity is described by Keegan (2011). Other more structured examples include 'Invisible Buildings' (Winter & Pemberton, 2011) and 'Savannah' (Facer et al., 2004.) Virtuality also extends to virtual pets (Hildmann, Uhlemann & Livingstone, 2008.)

CONTENT

Figure 5 shows the subtree from the Mind Map that explores the overarching theme of 'Content'. Content in mobile learning systems is usually targeted to a specific curriculum subject, and for the purposes of the Mind Map these have been grouped according to the Library of Congress classification (Library of Congress, 2014). Sciences are well addressed in mobile learning, for example mathematics has frequently been the target of mobile learning systems, as it can take advantage of various affordances of mobile devices such as calculators and sensors, and many mathematics learning systems are based on the ability to take the device outside the classroom and apply mathematical problem solving to real world contexts (Tangney et al., 2010.) Other major science classifications addressed by mobile learning include chemistry (Dekhane & Tsoi, 2012) and biology (Liu et al., 2009). Subjects from science subclasses have included nuclear power (Chang, Wu & Hsu, 2013) while subclasses from the social sciences have included awareness of traffic violations (Lan & Huang, 2012.) Further main classifications that are well represented in the mobile learning literature are world history (e.g. Wake & Baggetun, 2009) geography (Chang et al., 2012), and language and literacy, where mobile learning has proved particularly popular for learning languages, especially English. For example Cavus & Ibrahim (2009) used SMS for those learning English as a foreign language.

Mobile learning systems targeted at the professional learner will have content oriented towards skills, such as medical (Edwards et al. 2007; Havelka, 2011) or teaching skills (Seppälä & Alamäki, 2003). Not all content is specific to a curriculum subject or professional skill. For example Chiauzzi et al (2008) focus on the personal development topic of stress management. More generic types of content covered in mobile learning include learning schedules and cross cultural communication.

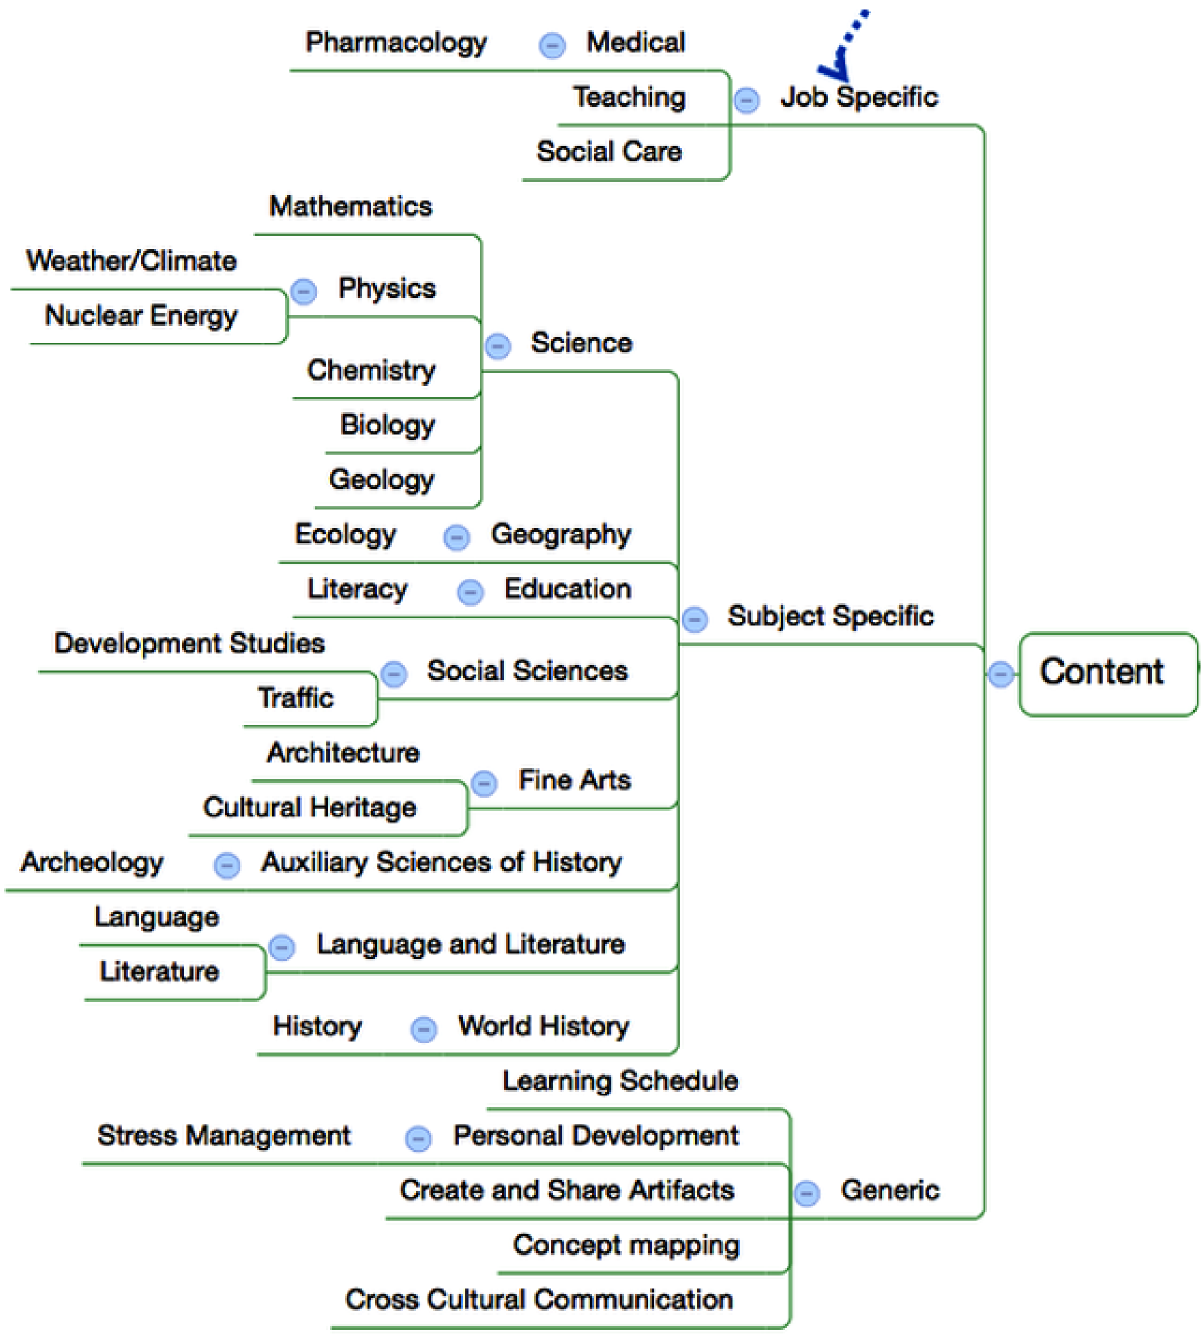
LEARNING

Figure 6 shows the subtree from the Mind Map that explores the overarching theme of 'Learning'. The learning category has been subdivided into style and context, with context further subdivided.

There are many learning styles, for example game-based learning which has been suggested holds the attention of young learners and motivates them (Kumar et al, 2010). The concept of scaffolding (from Bruner) is intended to support the initial stages of a learning process, and can be embedded in the design of mobile learning tools (Chen, 2003). Many authors distinguish between formal and informal modes of learning (e.g. Santos & Ali, 2012). Some learning styles are targeted at the individual, some at the group. Individual mobile learning addresses issues such as self-regulated learning (Sha et al., 2012), while other approaches emphasise collaboration and group work (Bowman, 1998), and the supporting of learner communities.

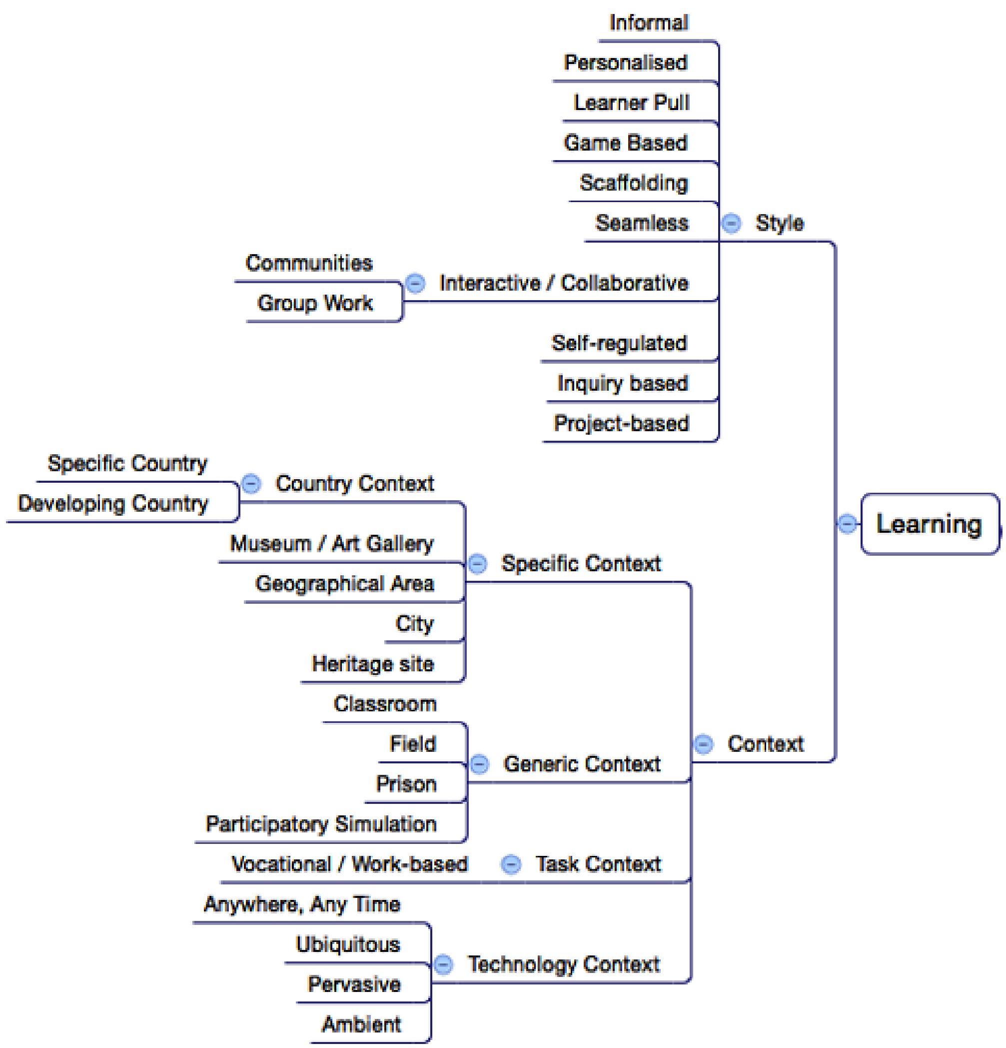
Within the context category, we make a distinction between general types of context and specific learning locations. For example, the classroom is one type of context, which relates

Figure 5. The 'Content' branch of the Mind Map



to the general concept of using mobile devices inside the classroom; the actual location of the classroom is not relevant. In contrast, the specific physical location (which may range from a local to a national context) is an important feature of many mobile learning experiences. A further task context is one in which a particular work-based task is to be performed. This is categorised as a separate context, since it may be relevant to both generic and specific situations.

Figure 6. The 'Learning' branch of the Mind Map



Though we have separated out styles and contexts they may of course overlap. For example Hung (2002) draws connections between situated cognition and problem-based learning (PBL) with educational technologies, and Uden (2007) discusses the relationship between collaborative learning using mobile technologies and the concepts of distributed cognition.

For learning in specific context, mobile devices naturally extend their learning support to outdoor learning environments. One of the most effective ways to teach subjects such as geography and heritage is through situated field study (Ahmad & Pinkward, 2012; Nordmark & Milrad, 2012). Where learning is situated in this way, location awareness is often a key component, whether indoor or outdoor (Brown et al, 2010.) Cook's (2010) concept of the augmented context for development in mobile learning applications integrates Vygotsky's zone of proximal development into location based learning activities.

Although our mind map includes a separate 'Technology' category, we also include a 'Technology Context' here, because specific types of technology environment can shape particular types of learning. A simple example is 'anywhere, anytime' learning, which depends on seamless technology infrastructure. A number of articles that explore more specialised technological contexts refer to terms such as ubiquitous, pervasive and ambient learning. These terms can be difficult to pin down, and in some cases may be used interchangeably. For the purposes of our analysis, we defined the terms as follows:

1. **Ubiquitous Learning:** learning that takes advantage of ubiquitous technologies, with technology integrated into the objects and activities of learning (Ogata et al, 2010).
2. **Pervasive Learning:** Where the technology penetrates or affects everything in the learning process. Thus it may be seen to be perhaps more specifically mobile than ubiquitous technology. For example it may involve bringing a mobile learning game into a particular environment (Laine, et al 2010). A consequence of this is that pervasive learning is also likely to be aware of its context (Syvänen et al, 2005).
3. **Ambient Learning:** Where the learning technologies are in the surrounding environment, For example the learning context might include sensors, tags, geotagging, interactive bar codes etc. (Price & Rogers, 2004).

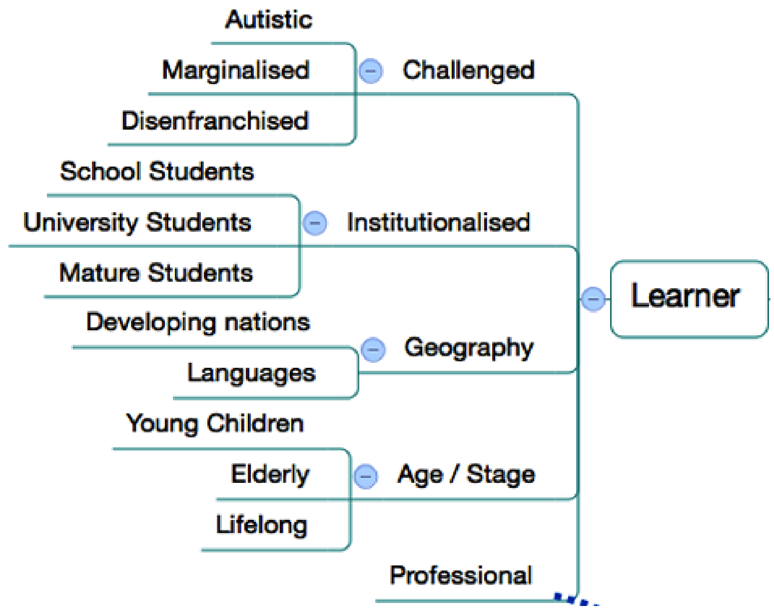
LEARNER

Figure 7 shows the subtree from the Mind Map that explores the overarching theme of the 'Learner'. Mobile learning solutions cannot be considered independently of the learner group for which they are intended. The learner category is mainly concerned with particular groups of individuals whose physical or social constraints lead to specific goals and needs. Groups of learners might be categorised in number of ways, for example by age, nationality, language or role, among many other possible categories. Age is an important learner category, because content and learning style need to be age appropriate. This does not just mean differentiating between the stages of institutionalised schooling, such as higher education (Alexander, 2004) or school, but may also involve other age groups outside of formal institutions, such as the elderly (Lam & Chung, 2009). Neither is the learner necessarily being targeted in the mainstream of education provision, since they may be challenged in some way, for example they may be marginalised (Unterfrauner & Marschalek, 2009). The nationality and/or language of the learner can also be a major factor, since some mobile learning applications are designed for a particular country or wider geographical context, often focusing on issues in developing countries, such as in Africa (Traxler & Leach, 2006; Lwoga, 2012), or India (Kumar et al., 2010), while others are specifically about teaching foreign languages (Viberg & Grönlund, 2013). Another important learner type is that of the professional learner, whose mobile learning needs may often be focused on learning support in context, or specific professional training. Common categories of professionals targeted by mobile learning systems include teachers (Seppälä & Alamäki, 2003), medical workers (Edwards, Jones & Murphy, 2007; Havelka, 2011; Pimmer et al. 2013) and those in the military (Metcalf & De Marco, 2006), or even a combination of military and medical (Han, Harkke, Collan & Tétard, 2006). Further categories of learner include prisoners (Murphy, Bedford & Farley, 2014) and the disabled (Rainger, 2005, Brown et al., 2011).

CONCLUSION

This article has approached the field of mobile learning research from a perspective of creative visualisation. A timeline has revealed notable stages in the evolution of research, from pioneering concepts and activities, through large scale national and international projects, to maturing forms of dissemination, with an underpinning

Figure 7. The 'Learner' branch of the Mind Map



process of technological change. The mind map has shown the breadth of research, its core themes, and some indicative work. This shows how mobile learning research is sometimes of the moment (many of the technologies used in past research are now obsolete) or very specialised (e.g. teaching a very specific topic) but may also address long term issues of teaching and learning theory and practice.

What conclusions might we draw from this analysis? From the timeline we can see that mobile learning as a research field has evolved through a series of stages, in which researchers have often provided the vision for the future that has later been met by the technology. Eventually, Alan Kay's vision for the Dynabook could be implemented in hardware and software. Pioneering researchers brought new devices into the classroom, and ultimately the learners began to bring their own devices. From these cycles we can see that the main role of the researcher is to create visions for the future. These visions may not be very practical in the short term, but give direction and impetus to others who can bring these ideas into mainstream learning. The message from the timeline for current researchers is to cast their eye beyond current technology and practice and imagine the potential opportunities for the mobile learning that are not yet even possible or practical.

From the mind map we can see that the field of mobile learning is very broad and researchers have already explored a multitude of theories, applications, topics and tools. Nevertheless there are great future opportunities. New technologies arrive all the time, enabling us to explore new ways to learn with these tools. There are many mobile learning applications that have addressed the core categories of the Library of Congress classifications, yet there are many sub-classifications that have yet to gain the benefit of innovative, specialised mobile learning applications. Many theories have been applied to mobile learning, yet there still seem to be ample opportunities for researchers to reinterpret existing theory in this research context, and to evolve new theory as the field matures and evolves. Perhaps the lesson that we might draw from the mind map is that, whilst some aspects of mobile learning have been exhaustively covered, there are always new branches that can be added to this tree of concepts.

There are of course a number of limitations to this work. While the literature coverage is broad it is by no means exhaustive. The categorisation is also largely subjective and is not quantitative. It would be interesting to see how this creative mind mapping technique might reveal very different interpretations of similar source material, if used by other researchers. More objective, qualitative analyses, perhaps measuring impact, would also be of value.

Despite its limitations, it is hoped that this article will be useful to new researchers seeking to understand the background to the research field, and find areas of research that are of interest to them. It may also act as a guide to aspects of mobile learning that have not yet been reported in detail in the literature. For existing mobile learning researchers, perhaps this contribution will help them to contextualise their own work within a broader vision of mobile learning, and thus give them inspiration for extending their future work into new areas.

Chapter 13
Factors Related to Students' Performance of Hybrid Learning in an English Language Course

Saovapa Wichadee
Bangkok University, Thailand

ABSTRACT

Redesigning a course along the lines of a hybrid format that blends face-to-face and online learning brings about changes in instructional practice. This paper introduces hybrid teaching that uses multiple web-based tools to supplement the students' face-to-face learning environment in a difficult situation in Thailand. In order to examine factors related to student learning achievement in the hybrid teaching course, data regarding learning achievement score, amount of participation, comfort with technology, and course satisfaction were collected from 182 students enrolled in an English course and analyzed by using correlation coefficients and multiple regression analysis. The findings indicated that students had a moderate level of satisfaction with the hybrid course and comfort with technology use, and previous experience of hybrid courses did not have an effect on their satisfaction. Student learning achievement was positively correlated with how much participation students had, but was negatively correlated with students' comfort with technology. There were no correlations between student learning achievement and how satisfied they felt with the hybrid course. In addition, an analysis of benefits and drawbacks of this hybrid course allowed teachers insights into what changes were needed when adjusting the hybrid course for language teaching.

INTRODUCTION

Nowadays, applying technology in the learning process is growing fast. There is an increasing integration of web-based resources into instructional practice (Rodriguez, Ooms, & Montanez, 2008). So, new learning environments and teaching methodologies based on the utilization of information and communication technologies such as e-learning, web-based learning, open and distance learning, and hybrid learning have been introduced in many courses. The face-to-face courses in conventional format have been modified to increase more on-line learning environments

DOI: 10.4018/978-1-4666-8246-7.ch013

called 'hybrid teaching.' Hybrid teaching is a combination of formal class meetings and virtual learning to promote active, self-directed learning opportunities with added flexibility (Garnham & Kaleta, 2002). In a hybrid course, conventional learning is enriched with the use of appropriate learning technologies. An instructor reduces in-person classroom meetings and replaces a significant amount of that instructional time with online learning activities (Allan, 2006; Orhan, 2008).

Since the goal of a hybrid approach is to join the best aspects of face-to-face and online instruction, there are many benefits for both teachers and students. First, a hybrid approach provides flexibility and convenience for students to work and communicate with others. Students have a wide range of socio-emotional messages to convey their personal greetings, feelings, and humor which resulted in more interpersonal relationships (Fjermestad, Hiltz, & Zhang, 2005). Second, a hybrid course enables teachers to organize their teaching in a meaningful way. That is, face-to-face oral communication can be designed to integrate well with online written communication so as to serve the context and intended educational purposes (Graham, 2005; Bonk, Kim, & Zeng, 2006). Classroom time can be used to engage students in content which suits a face-to-face environment. Meanwhile, the online portion of the course can provide students with content at anytime and anywhere, depending on the needs of the students and the preferences of the instructor.

Teaching a hybrid course is a challenging task since it requires both online and face-to-face teaching skills. On-line activities mostly provide links to resources and downloadable text materials, administer online quizzes and electronic submission of assignments (Dabbagh & Bannan-Ritland, 2005). So, teachers new to technology need to study how to facilitate online learning to assist students in keeping their work on track and should find technical support on campus for themselves and for their students (Lin, 2009). Incorporating technology in the course depends on the relative opportunities and constraints of its learning environment. For example, teachers may consider whether the course content and learning technologies are matched. Also, teachers should manage face-to-face classes to suit activities relating to verbal communication and body languages transmitted in a real-time.

Based on a literature review, it was found that hybrid teaching environments produced satisfactory results. Many studies revealed positive influences of hybrid learning on student performance (Ladyshewsky, 2004; Motteram, 2006) and student participation (DeGeorge-Walker & Keeffe, 2010; Lopez-Perez, Perez-Lopez & Rodriguez-Ariza, 2011; Ugur, Akkoyunlu & Kurbanoglu, 2011). Moreover, Wu and Hiltz (2004) found that hybrid courses that utilized asynchronous means of communication improved students' perception of learning. According to Bhatti, Tubaisahat, and El-Quawasmeh (2005), student satisfaction about learning increased while the students' dependency on the instructor for assistance decreased. They explained that online materials provided students with the resources to seek out answers independent of the instructor. Moreover, Rodriguez and Anicete (2010) examined students' views of hybrid learning in an undergraduate Ecology course, which incorporated Modular Object Oriented Dynamic Learning Environment (MOODLE) into the online portion of the coursework. Results revealed that a majority of students had positive views and experiences with hybrid learning, despite some challenges. Implications were discussed in terms of how to better utilize this instructional format in general education courses to foster active learning.

Rivera, McAlister, and Rice (2002) surveyed student satisfaction among the three modes of learning (face to face, fully online, and hybrid) and found that student satisfaction was the highest with the hybrid learning model and that test scores were the same for all three methods of delivery. Young (2002 cited in Buzzetto-More & Sweat-Guy, 2006) examined hybrid and fully online teaching at several universities and concluded that among the three modes of instruction (face to face, fully online, and hybrid), hybrid model offered the most significant benefits for teaching and learning. Hybrid teaching produced more active and deeper learning when compared with the traditional classes (Donnelly, 2010; Woltering, Herrler, Spitzer & Spreckelsen, 2009).

Aforesaid literature review with positive outcomes of hybrid teaching strengthened our beliefs and confidence in creating hybrid course experience for students at Bangkok University. Hybrid courses were designed to solve the problem of inadequate classrooms with a hope that it could help increase students' learning the same way as the traditional method had done in the past. In October 2011, Thailand faced the serious flooding situation which caused trouble for many people. Most offices and educational institutions had to close themselves for about 2-3 months. Bangkok University was no exception. The opening of the second semester was postponed many times due to the huge flood. The university administrators worked very hard to solve this problem; they tried to reorganize the schedule to keep instruction going. However, classrooms were not enough for the upcoming semester because most of them needed repair and refurbishment. The lack of classrooms still remained the big problem. The administrators had held several meetings to find out the best solution, and they came up with the concept of "hybrid instruction." With hybrid teaching, faculty members can use a variety of online and in-class teaching strategies, making it possible to achieve course goals and objectives effectively. It was hoped that the hybrid model or the blended learning approach to teaching would allow us to develop solutions to course problems and to incorporate new types of interactive and interesting learning activities. As such, the setback from the huge flood was turned into a good opportunity for Bangkok University students to make use of their technological skills to gain knowledge. With the hybrid model which offers the most substantive benefits for teaching and learning, students would become autonomous learners (Chapelle, 2001). Simultaneously, the advent of technologies in computer networking has enabled language teachers to shift their practice in using computers for their teaching.

Although hybrid instruction was the only one choice we had during that time, it was beneficial to find out whether the designed format is really satisfied by our students since design has a significant impact on how students approach learning (Graff, 2003). When designed carefully, a hybrid course combined the best features of in-class teaching with the best features of online learning to promote active student learning (Lin, 2008). According to McFarlin (2008), the hybrid course format can increase students' exposure to course content, thereby improving their academic performance. At the end of the course, students' perception was, therefore, examined. Does the hybrid course help to motivate student learning or make them succeed in learning? Since technology-based learning is a part of hybrid teaching, it is necessary to take students' feeling and technical skills into consideration. So, two factors including students' satisfaction with the hybrid course and comfort with technology cannot be ignored as they may have something to do with students' participation in learning and achievement. A previous study revealed a positive correlation between students' visible learning behaviors, such as participating in online activities, and their learning outcomes (Wang, 2004). In some pieces of research, it was found that comfort with technology was related to satisfaction with on-line learning (Stokes, 2003), and there were several factors to be considered while developing or implementing e-learning based courses such as technical competency, and university support (Selim, 2007). For students with on-line learning experience, comfort with technology was related to satisfaction with online courses (Rodriguez, Ooms, & Montanez, 2008). The finding in one study showed that motivation had a significant relationship with on-line participation (Xie, Durrington, & Yen, 2011).

The more motivation students had, the more they participated in the on-line course. Since on-line learning is a part of the hybrid format, the current study cannot exclude the factor of comfort with technology. The results of this study will reveal whether students perceive the hybrid approach as an effective or satisfactory way of teaching and what factors are related to their learning performance. The information derived from the study will be useful for the administrators in adjusting the hybrid course of Fundamental English to suit students' need. Also, the findings will be useful for instructors interested in implementing hybrid courses. The factors which were found to be related to students' performance should be taken into consideration. The four research questions guiding this study included:

1. What are students' learning achievement, satisfaction with the hybrid English teaching course, comfort with technology and participation?
2. Are there any differences in students' perceptions of hybrid English teaching course quality between two groups of students: one with experience with hybrid courses and the other with no experience with hybrid courses?
3. Are there any relationships between the students' learning achievement, satisfaction with the hybrid English teaching course, comfort with technology, and participation?
4. What are the drawbacks and benefits of hybrid teaching in an English course?

RESEARCH METHODOLOGY

The study design used a mixed-methods approach employing both quantitative and qualitative analysis of which the results could be compared and validated. Based on literature review, three independent variables—participation, satisfaction with the course, and comfort with technology were chosen to investigate the relationship with student learning achievement. In the quantitative analysis, the Technology Acceptance Model (TAM) was used to structure the data analysis. Davis (1986) who proposed the TAM model suggested that the ease of use and usefulness of a technology affect users' intention to use it. In this regard, comfort with technology and attitude towards hybrid course can have an impact on participation in online activities of the hybrid course. The more students participated in online activities, the more they had learning outcomes (Wang, 2004).

Satisfaction was chosen as a variable because when students are satisfied with the course, they often participate more. As a result, they are more likely to be successful (Allen et al., 2007; Puzziferro, 2008). It was defined as the student's perception that the course was a beneficial experience. Satisfaction informed how the course was accepted and valued, and it indicated the quality of the learning experience. Feedback from students should be obtained since it can throw light on the appropriate proportion of online and face-to-face components. In providing educational programs, people in charge use the information from course evaluation and participant feedback in making a decision of the delivery of the program (Wong & Yeung, 2003). One of the major criteria of such an evaluation process is to find out how satisfied the course participants are with the program, and this is often done through using a survey instruments (Pena & Yeung, 2011). Participation was another important variable which was counted by the number of attendance a student had, both in class and online. Comfort with technology was defined as the belief that using technology is comfortable or free of effort. The dependent variable was student learning achievement which can be measured by scores gained from assignments and a writing test. The qualitative analysis transferred from an open-ended perspective focusing on students' input on benefits and drawbacks of hybrid learning.

Participants

One hundred eighty-two students, from five sections of Fundamental English II participated in the research. All students who completed the course (i.e., did all assignments and took an in-class writing test) were included as participants. There were 123 females and 59 males. Eighty-three students came from School of Communication Arts, 40 students from School of Humanities, and 59 from School of Business Administration. All participants signed consent forms, and the instructor assured them that all data would be confidential and that the survey responses would not influence course grades.

Course Structure and Assessment

This study took place at a university in Thailand between January and April 2012 when the course of Fundamental English II was designed for hybrid teaching. It was a 3-unit credit course that met three hours weekly within a 14-week period. This course was usually taken by undergraduate students from different faculties during second semester. Student learning achievement was measured by an in-class writing test and the completion of homework assignments. The total score for grading was 100.

Research Instruments

The impact on students' learning was evidenced by three instruments. The first instrument was a report of learning achievement score and an amount of participation. The second instrument was a questionnaire covering four main parts. The first part asked the participants to give their background information comprising gender and experience in taking hybrid courses. The second part surveyed students' satisfaction with the hybrid course in order to learn how well the course was accepted by the students. It comprised 8 items with a choice of five rating scale responses for each (5 = strongly agree to 1 = strongly disagree). This part also required the participants to rate how much they agreed that the hybrid course meet the same quality standards as a classroom course with a five-point Likert scale ranging from strongly agree to strongly disagree. The third part asked the participants to rate their comfort with some commonly used technology applications on 10 items with a choice of five rating scale responses for each (5 = strongly agree to 1 = strongly disagree). This part was taken from the questionnaire in the research study conducted by Rodriguez, Ooms, & Montanez (2008). The last part provided two open-ended questions. The participants specified what they viewed as the three main benefits and the three main drawbacks of teaching with the hybrid format. The third instrument was an English proficiency test comprising reading and writing skills. The total score was 20 points. The contents for testing students were written to cover EN 112 contents in terms of vocabulary, grammatical points, summary writing, and paragraph writing. So, there were three main parts: 1) read a story and answer 5 questions 2) read a story and write a summary in 3-5 sentences 3) write a well-organized paragraph in about 100 words. Time allotted for the test was 100 minutes. The items of the tests were examined by three teachers of English from the Language Institute to assume language accuracy and content validity.

Internal-Consistency Reliability

The Likert scales items in part 2 and 3 of the questionnaire were processed for determining an internal consistency with 40 non-subject students by the coefficient alpha technique. Two parts in the questionnaire yielded acceptable coefficient-alpha estimates with the reliability value of .85 and warranted their use for the purposes of this research study (Cronbach, 1951).

To ensure the fairness in scoring the test, this study employed three examiners including two experienced teachers and the researcher to mark

Table 1. Scoring rubric for summary writing

	4	3	2	1
Main Idea	Effectively communicates the main idea of the reading selection	Communicates the main idea of the reading selection	Unclear presentation of the main idea of the reading selection	No main idea is presented
Supporting Details	Clearly identifies the most important details	Presents most of the important details	Presents details but leaves out some important details	No supporting details are presented
Use of Paraphrasing	Contains successful paraphrasing of main points, and avoids copying	Contains mostly successful paraphrasing of main points	Contains minimal paraphrasing with some copying of key phrases	Little or no paraphrasing and substantial copying of key phrases
Sentence Structure	Consistent use of complete, coherent sentences	General use of complete, coherent sentences	Inconsistent use of complete, coherent sentences	A lot of incomplete or incoherent sentences
Spelling	Excellent spelling	Generally good spelling	Inconsistent spelling	Errors in spelling that interfere with reader's understanding

the writing papers. The inter-rater approach of reliability estimates was applied to find the reliability of scores which were .887 (rater 1-2), .828 (rater 2-3), and .856 (rater 3-1).

This study employed three raters for grading writing assignments. In order to confirm the reliability of scores, the inter-rater approach of reliability estimates was applied. That is, the correlation coefficients between three different raters were calculated, and the results were .964 (rater 1-2), .875 (rater 2-3), and .928 (rater 3-1).

Rubrics for Grading Assignments

The rubric used for grading summary writing was mutually created by all of the teachers. The full rubric score was set at 20 points which would be divided by four to get five points for each piece of writing (Table 1).

In grading a descriptive paragraph, ten points were allocated to five categories. Then the obtained score was divided by two in order to get the full score of ten (Table 2).

The score allocation for the writing assignment "giving opinions on a movie" was ten points. Content and language use were two categories to be graded. The full rubric score was set at 20 points which would be divided by two to earn ten points (Table 3).

Teaching and Learning Procedure

In developing an appropriate hybrid format, the previous course syllabus had to be redesigned to cover online and in-class contents. Even though the use of Internet technologies blended with face-to-face class format can produce a wide variety of models, for the Language Institute, teachers in all courses followed the same pattern of two weeks of lecture, three weeks of WebEx Video Conference, two weeks of Learning Management System, and seven tutorial classes due to classroom limitation. In week 8, some of the classrooms were expected to be ready for tutorial classes where two subjects were taught in the same room. The proposed model was shown in the schedule presented in Table 4.

In our design, instructional process needs to begin with team teaching as we see a lot of benefits of this approach. First of all, team-teachers share responsibilities and thus lighten each other's workloads, especially in the large-size classes.

Table 2. Scoring rubric for descriptive paragraph writing

	4	3	2	1
Topic sentence	The topic sentence has a clear idea and it is easy to understand.	The paragraph contains the topic sentence, but it is simply a restatement of the topic.	The paragraph has the topic sentence, but it is unclear or contains fragments.	The paragraph does not contain a topic sentence.
Paragraph Body	The body of the paragraph supports the topic sentence with meaningful details.	The body of the paragraph supports the topic sentence, but it is short on specific details.	The body of the paragraph does not support the topic or is a list.	The paragraph does not contain a body.
Length	The paragraph consists of 10 or more complete sentences.	The paragraph consists of 7-9 complete sentences	The paragraph consists of 4-6 complete sentences	The paragraph consists of 3 or fewer sentences
Grammar & Spelling	Consistent use of correct grammar with excellent spelling	General use of correct grammar with generally good spelling	Inconsistent use of correct grammar with inconsistent spelling	Incorrect use of grammar and errors in spelling that interfere with reader's understanding
Closure	The paragraph has clear closure that is distinct from the topic sentence.	The closure is a variation of topic.	The closure is a restatement of the topic.	The closure is not related to the topic or there is no closure.

Adapted from http://www.rcampus.com/rubricshowc.cfm?sp=true&code=G85X56&

Second, team-teachers can improve the overall quality of the language lesson as the teaching job is assigned to each teacher based on their strong points. As such, team teaching can provide opportunities to make the best use of each teacher's ideas and experiences. Lastly, team-teachers can show students how teachers cooperate with each other. For EN 112, team-teaching in a large class was very useful when there were not enough classrooms. About 200 students were gathered in a big room and taught by team-teachers for the first two weeks.

The second component which is new for all teachers is WebEx: video conference system. WebEx is designed to be a virtual classroom where the teacher and students can meet and talk. With a camera and microphone, an interaction between both sides can occur based on a pre-set schedule. Video conference system helps students save time traveling to campus. It also solves the problem of limited classrooms. Students are required to participate in on-line classes for three times as scheduled. To earn 10 points, they were to speak, share ideas, ask or answer the questions.

Table 3. Scoring rubric for opinion paragraph writing

Criteria for Evaluation	Rating
Part I: Content	
The first paragraph presents brief information of the movie: movie's name, director, and stars (2 points)	2-1
The second paragraph reviews the story of the movie: the plot and theme (5 points)	5-4-3-2-1
The third paragraph gives opinions on the movie (3 points). The opinion must be biased: whether students like the movie or not. Give reasons to support the opinions.	3-2-1
Part II: Language Use	
Complete sentences are written instead of run-ons or fragments.	5-4-3-2-1
Grammar, punctuation and spelling are used appropriately.	5-4-3-2-1

Table 4. The proposed hybrid learning model

Week	Types of Teaching
1 & 2	Big class made up from many sections (team teaching)
3,5 & 7	WebEx: video conference system
4 & 6	Self-study online materials in Learning Management System
8-14	Tutorials: student-teacher small group meetings (10 students/40 minutes)

The next component in this hybrid teaching course includes Learning Management System (LMS). It refers to a server-based software that controls access and delivery of online learning resources through a standard web browser. In this study, students are required to study online materials, do quizzes, and summarize three stories, each of which was worth 5 points. The assignments are to be submitted in Learning Management System. LMS can show scoring and tracking of students' progress. Two means of communication available for teachers and learners include the announcement and discussion boards. Announcement is used to give all students any new information about the course, including the latest news and upcoming events while the discussion board is a forum of communication where both teachers and learners can post their messages and read the comments from others. In this study, after self-studying the materials provided, students did some exercises for their understanding.

Seven weeks (Week 8-14) were provided for tutorial classes. Instruction in tutorial classes is arranged in a small group format, providing an opportunity for students to brainstorm ideas and receive feedback on written drafts. This makes the actual writing process less burdensome. Teachers can identify the strengths and weaknesses of individual students, help them develop understanding and improve their attitudes of learning English. Tutorial classes are scheduled in the last step of hybrid format with a hope that classroom repair will be done during that time. Students in a group of 10 came in the class on a certain period of time based on the pre-set schedule distributed to them. They had a good chance to practice writing and get feedbacks from their teacher right after they finished writing. Individually, they wrote a 10 sentence paragraph describing a place for tourists to stay while on vacation in Thailand. Students were required to submit their first draft on week 8 in class and then the final draft on week 10. Next, they had to study an online material "Giving Opinions on a Movie." Then they individually watched a movie of their own interest and wrote a review of that movie. The review included THREE paragraphs: presenting brief information of the movie: movie's name, director, and stars, reviewing the story of the movie: the plot and theme, and giving opinions on the movie. Finally, students had an in-class test on writing.

Data Analysis

Data were collected from the questionnaire and the assessments of the students' assignments in form of score report. For the quantitative analysis, a one sample t-test, means and standard deviations were used to analyze students' learning achievement, satisfaction with the hybrid course, and comfort with technology. Frequency and percentages were used to investigate students' participation and opinion on the quality standards of the hybrid English course when compared with the conventional course. In addition, an independent samples t-test was employed to find out whether any difference existed in the two groups: one with experience with hybrid courses and the other without experience of hybrid courses. Pearson Correlation Coefficients were used to study the relationships among students' learning achievement, participation, satisfaction on hybrid course, and comfort with technology. Then linear regression was used to find out factors which might be predictors for student learning achievement. Open-ended questions included within each section of the questionnaire were read, coded, re-read, and categorized into bins by question (Miles & Huberman, 1994).

Table 5. The result of learning achievement scores

n	Mean	S.D.	Maximum	Minimum	Criteria	t	p
182	72.52	14.09	93	14	70	2.425	.008

RESEARCH RESULTS

Part I: Students' Learning Achievement, Participation, and Perceptions

Research Question 1: What are students' learning achievement, satisfaction with the hybrid teaching course, comfort with technology and participation?

Students' learning achievement was assessed from their scores obtained from all assignments and in-class test. The mean score was 72.52 from 100 with standard deviation of 14.09. The highest score was 93 while the lowest score was 14. After comparing the mean score with the criteria which was set at 70 by the Language Institute, the result from one sample t-test analysis showed that the mean score of 72.52 was higher than the criteria at the significance level of .05, indicating that students' learning achievement was satisfactory (Table 5).

Table 6 showed that there were two students (1.1 per cent) who only participated twice throughout the course. There were 33 students (18.1 per cent) who participated every time.

Table 7 showed the overall mean score of satisfaction with the hybrid course which was at moderate level (Mean = 3.16). The first highest mean score fell on item no. 6 (Learning Management System), followed by item no. 3 (team-teaching), and item no. 4 (Tutorial classes). The lowest mean scores were on items no. 2 and 8 (the format of hybrid and materials on-line). All of the items were at a moderate level.

Table 8 demonstrated the overall mean score of students' comfort with technology which was at a moderate level (Mean = 3.42). When considering each item, it was found that the three activities students got involved in the most were chatting on-line, receiving documents electronically, and accessing the Web. These three items were at a high level:

Research Question 2: Are there any differences in students' perceptions of hybrid teaching course quality between two groups of students: one with experience with hybrid courses and the other with no experience with hybrid courses?

From the survey, students were divided into two groups: the ones with hybrid learning experience and the others with no hybrid learning experience. They were asked to rate the quality of hybrid English course when compared with conventional courses. The result revealed that the percentage of students expressing their agreement was similar in both groups. That is, 28.8% of students without hybrid learning experience and 26.9% of students with hybrid learning experience agreed that the hybrid English course had the same quality standards as traditional courses. However, the number of students without previous experience who showed their disagreement with the quality standards was higher than that with previous hybrid learning experience (Table 9).

An independent t-test analysis was employed to examine a significant difference between two groups of students in their perceptions. The results revealed that there was no statistically significant difference found in students' perceptions between two groups at the level of .05. This means that students with and without experience in hybrid courses were not different in their perceptions on quality standards of this hybrid English course compared with conventional English courses as demonstrated in Table 10.

Table 6. Number and frequency of students' participation

Frequency of Participation	Number of Participants	Percentage
2	2	1.1
5	1	.5
6	3	1.6
7	1	.5
8	7	3.8
9	12	6.6
10	27	14.8
11	16	8.8
12	44	24.2
13	36	19.8
14	33	18.1

Variable	n	Mean	S.D.	df	t	p
With hybrid learning experience	78	2.94	.97	180	.413	.680
With no hybrid learning experience	104	2.88	.99			

Part II: The Relationship between Some Factors and Student Learning Achievement

Research Question 3: Are there any relationships between the students' learning achievement, satisfaction with the hybrid teaching course, comfort with technology, and participation?

The primary purpose of this study was to examine the relationship between some factors and student learning. Participation was calculated based on the number of times they attended classes including on-line and face-to-face classroom. Student learning was measured by the total points earned out of 100 (Mean = 72.52, S.D. = 14.09). Several analyses were, therefore, conducted to assess some factors which related student learning in the hybrid teaching course. Findings revealed that student learning achievement was positively correlated with how much participation students had, $r = .625$, $p < .001$. That is, the more students participated in the hybrid class, the higher their learning achievement.

It was interesting to see that the factors of comfort with technology and satisfaction did not have an influence on hybrid learning achievement. From data analysis, there were no correlations between student learning achievement and how satisfied they felt with the hybrid course, $r = -.017$, $p = .819$. Negative correlations were found between comfort with technology and their learning achievement, $r = -.220$, $p < .01$.

The results also indicated that course satisfaction was not correlated with how much participation students had, $r = .059$, $p = .429$ and comfort with technology, $r = .030$, $p = .687$. However, it was found that there was a negative correlation between comfort with technology and participation, $r = -.179$, $p < .05$. See Table 11.

After that, the relationship was analyzed by using linear regression. In order to find out which factors could be predictors of learning achievement, satisfaction with the hybrid course and comfort with technology were entered into the regression equation as independent variables along with participation. Then it was found the linear combination of these variables was significantly related to learning performance, $F = 43.75$, $p <$

Table 11. Intercorrelations among variables

	Participation	Satisfaction	Comfort with Technology
score	.625***	-.017	-.220**
Participation		.059	-.179*
Satisfaction			.030

*Correlation is significant at the 0.05 level (2-tailed)
** Correlation is significant at the 0.01 level (2-tailed)
*** Correlation is significant at the 0.001 level (2-tailed)

Table 12. The influence of predictor variables, including satisfaction with the hybrid course, participation, and comfort with technology

Predictor Variables	Unstandardized B	Standardized Beta	t	p
Constant	37.710			
participation	4.20	.627	10.82	.000
satisfactory	-1.51	-.062	-1.08	.280
Comfort with technology	-2.42	-.099	-1.72	.088

.001, R2 = .424. The adjusted R square was .415. This means that the three significant predictor variables accounted for 41.5% of the variance. Participation was the only one statistically significant predictor to student learning, $\beta = .627$, $t = 10.82$, $p = <.001$. Table 12 illustrates the relative contributions of each predictor variables to the significant predictive model.

Part III: Open-Ended Responses

Research Question 4: What are the drawbacks and benefits of hybrid teaching?

The final section of the questionnaire asked the participants to respond to two open-ended questions. First, they were asked to specify, in order, what they perceived as the three main benefits to learning with a hybrid format. Participants replied that the most significant benefit was the flexibility the hybrid format had, permitting them to have more freedom. They did not need to come to the campus when they studied on-line. The second most important benefit was gaining more responsibility and self-discipline when they were assigned to do out-of-class assignments or to prepare themselves before attending WebEx video conference sessions. Lastly, students indicated that they gained a lot of benefits from tutorial classes where they could get more explanation in a small group. The kind of face-to-face tutorial class was better arranged than the traditional face-to-face class, resulting in more motivation to learning.

Second, the participants were asked to list, in order, what they believed to be the three main drawbacks of studying with a hybrid format. Regarding the most significant drawback, students specified technical problems occurring when they studied through WebEx. Mostly, students who used equipment at the Language Lab on campus could not communicate well because of equipment defects such as microphones, speakers, and cameras. Participants stated that the second most significant drawback was the amount of time spent working with others on two projects and studying materials in the Learning Management System. In order to complete the course requirements, students complained that they had to do so many activities. Lastly, the participants mentioned having no face-to-face interaction during on-line learning. This made them have stress and anxiety, especially, when they did not know what to do with the assignment. The discussion board was not convenient in case they required a lot of explanation. However, the situation turned better when students started tutorial classes.

DISCUSSION

Although the findings show that students' learning achievement is satisfactory (Mean = 72.52), many issues should be taken into discussion when developing hybrid teaching courses of English. The first discussion concerns frequency of participation in this hybrid course. The results of regression analysis clearly showed that success in the class was positively related to the amount of participation. It might be because hybrid teaching allowed the flexibility and efficiency of the online environment, so students have access to content and assignments on their own time. On-line learning gave a chance for students to revise their lessons all the time and in all places, and when they had some enquiries concerning contents and exercises, they could ask instructors through WebEx and the discussion board in Learning Management System. In addition, they gained more understanding about projects and writing in tutorial classes because they could ask the teacher for clarification and discuss with peers in a small group. The response to open-ended questions showed that students liked tutorial classes although they had never experienced them before. In this way, the blending of face-to-face and technology-supported out-of class activities becomes a "mechanism through which students engage in existing effective educational practices" (Laird & Kuh, 2005).

The second discussion is about their satisfaction with the hybrid course of Fundamental English. It is essential to state that while the use of hybrid teaching can reinforce student learning, it does not bring about a high level of satisfaction. From the findings, students showed their satisfaction with the hybrid course of EN 112 at a moderate level. One of the causes may have been from the use of WebEx as they specified the most significant drawback. The video conference system should be used only when all the equipment is fully effective. From the interview, it was found that most students did not feel impressed with communicating online through video conference. In addition, they seemed to have less connected during on-line learning with Learning Management System. Apart from that, there are many other elements of the learning context students may consider such as subject contents, communication, process, and learning tasks.

One interesting issue is about student perceptions of quality of hybrid course when compared with a traditional course. In this study, students with hybrid learning experience were found to have the same agreement as others with no hybrid learning experience. When taking a closer look at their perceptions, students with and without experience in hybrid courses did not differ in their perceptions on quality standards of this hybrid English course compared with conventional English courses at the significance level of .05. A possible explanation for this result comes from Peterson and Bond (2004) revealing that students without hybrid learning experience may perceive that they learned more through face-to-face classes. They might remember traditional teacher-directed pedagogical learning environments where autonomous learning was not utilized. This is an interesting finding, suggesting that they might not be accustomed to learning independently. Meanwhile, students with hybrid learning experience who had been more familiar with online learning did not have different perception as well. Students in this group probably found the present course less interesting than the previous one they had ever taken, so they expressed their satisfaction at a moderate level. This result is supported by Graff

(2003) who states that design has a significant impact on how students approached learning. A hybrid course which is designed carefully can promote active learning (Lin, 2008). It can be concluded that students' prior learning experience did not affect their satisfaction and acceptance of the hybrid course.

That student learning achievement was not correlated with how satisfied they felt with the hybrid teaching course can be explained by two reasons. First, students were informed of the necessity of reorganizing the instructional process and limitation of classroom settings due to flooding. They understood that the difficult situation was the main cause of these changes. Second, learning English with hybrid format was rather new for many students who might not accept increased responsibility for their learning. The factor of learning styles can affect their satisfaction with the course. Some students prefer convenience and flexibility while the others don't. Moreover, having no chance to select communication tools may have an effect on student satisfaction too (Garrison & Vaughan, 2008). In spite of these limitations, the acceptance of the difficult situation made students pay much attention to the new course format and put more effort to their study in order to earn good scores.

The last issue for discussion is on students' comfort with technology. Although university students were expected to be proficient with online technology tools, the results of students' comfort with technology demonstrated only a moderate level. In addition, there were also negative correlations between comfort with technology and their learning achievement. The more students were comfortable with technology, the fewer scores they gained. This might be due to the fact that the hybrid course comprised not only on-line learning, but also face-to-face classes, so technological skills might not have much effect on student success. The result was in accordance with the open-ended responses showing that students felt worried about the anxiety they had when they wanted more detail about assignment and technical problems occurring when they studied through WebEx video conference. They did not specify any problems concerning their technological skills.

CONCLUSION

Due to the huge flood in our country, hybrid instruction became an alternative for all courses at the university. Therefore, the study was conducted to investigate the factors related to students' learning achievement after face-to-face meetings and online technology usage were blended in a fundamental English course. The findings reveal that participation is an important variable to be considered, so there should be a strategy to motivate students to participate more in both on-line learning and face-to-face classes. For example, the more they contribute to the activities, the more they will get the extra points. Some drawbacks expressed by students pointed out that technical problems such as insufficient computers and low-quality equipment were obstacles to communication which should have been solved before on-line learning started. The results from this study will be useful for instructors who may carry out a hybrid course in the near future.

LIMITATIONS OF THE RESEARCH

There are some limitations to be addressed in the study. First of all, the situation of huge flood occurring in Thailand was sudden; it did not provide us the possibility of having traditional face-to-face classes, so there was no control group to compare in terms of student learning achievement. Secondly, it has to be noted that the results should be considered in a cautious way as the study is applied in specific settings. One limitation is that while many variables were chosen to study, some variables such as university support in computer use on campus, economic situation, campus environment, and computer skills were not taken into account. These variables might have some influence on student learning outcomes and participation. In this study, inadequate computers resulted from adding on-line learning in many courses at the same time. Apart from that, many students had a financial problem because their parents faced difficulties. Another problem was that the environment on campus was not ready for a study; most buildings were under repaired. Also, hybrid teaching is not only a new instructional experience for students, but also for teachers. Some of them were not much skilled in technology. They had to learn how to communicate through video conference, create exercises and post on the discussion board in Learning Management System three weeks before the class started. For further study, the motivation factor is highly recommended to examine whether it has an effect on academic performance or not since the current research did not study students' motivation at all.

Chapter 14
Technology-Enhanced Learning:
Towards Providing Supports for PhD Students and Researchers in Higher Education

Eileen O'Donnell
Dublin Institute of Technology, Ireland

Liam O'Donnell
Dublin Institute of Technology, Ireland

ABSTRACT

There are many elements to an individual's life. Each individual engages in a variety of different activities which all require different types or forms of supports. Through family, friends, and colleagues, supports are available for many of the activities in which we engage. But, for students conducting research, specific types of support are necessary that can only be provided by supervisors and peers. This chapter reviews the supports necessary to learn how to effectively undertake research and how these supports could satisfactorily be provided through an e-learning portal or an e-learning platform. An e-learning module could be used to facilitate collaboration amongst student learners and researchers who share similar research interests. Students should be encouraged to develop a community of practice with fellow researchers as this relationship could provide beneficial peer support for as long as their research interests evolve and endure.

INTRODUCTION

This chapter investigates some of the issues which researchers encounter when performing their research and suggests that an e-learning module would assist researchers in overcoming these issues, "with the worldwide spread of journals in educational research, such technology-enhanced research has received much attention since the turn of the century" (Hwang & Tsai, 2011, p. 65). A Technology Enhanced Learning (TEL) or an e-learning module on research methods and statistical analysis is envisaged not as a replacement for existing structures to assist researchers, but as an enhancing technological solution to augment existing approaches through blended learning.

DOI: 10.4018/978-1-4666-8246-7.ch014

Technology has enhanced research through the ease of access to electronic journals and other citable electronic media. The use of word processing applications and referencing packages has made the writing up of research findings more efficient. The use of statistical analysis applications, spreadsheets, and database packages, has streamlined the process of analysing data, and the production of graphs and charts to illustrate the findings. The use of graphs and charts has greatly improved the readability and understanding of research outcomes. Communications between co-authors, editors and publishers through e-mail has greatly improved the flow and process of publishing academic research. Online submission of electronic papers has further enhanced the publishing process.

Technology enhanced learning (TEL) refers to the support of teaching and learning through the use of technology and can be used synonymously with e-learning, technology enhanced research has the possibility of supporting researchers and perhaps improving the quality of research. An e-learning module is stored in a predefined location on an e-learning platform and is dedicated to a particular subject area. Students are provided with user names and passwords to access and contribute to this module. Because the e-learning module is online students can access this module at any time from any place providing they have the appropriate computer equipment and broadband access.

While collaborating on papers and writing chapters of books, realisation dawned that a greater knowledge and use of research methods and statistical analysis was necessary to improve the quality of research and meet the requirements of peer reviewers. "Improving the quality of the student learning experience is a key issue in the higher education sector" (Dermo, 2009, p. 203). Power, Miles, Peruzzi, and Voerman (2011), and Parkinson (2009), suggest students can benefit from peer-to-peer mentoring in higher education. Hence, this book chapter proposes that an e-learning module on research methods and statistical analysis which encourages peer-to-peer mentoring could effectively support students and researchers and encourage peer-to-peer mentoring.

"Due to a lack of formal research training and experience, students can find completing research projects a daunting task. This, coupled with a fear of statistics, can culminate in quite an overwhelming experience for many students" (Chen, 2012, p. 1). When one commences study for a PhD (Doctor of Philosophy), generally a BSc (Bachelor of Science) and MSc (Master of Science) have already been acquired to a high level of academic achievement, conferred with a First or 2.1 Honours. Research methods and statistical analysis may not necessarily have been included in the subjects covered in the discipline undertaken or possibly some time has passed and a refresher course is required to update skills. Therefore there is perhaps a need for researchers to familiarise themselves with the correct application of research methods and statistical analysis techniques to their specific research area. Some researchers will have a good understanding of research methods and instinctively know which method or combination of methods to apply to specific research, while other researchers may need guidance and support in the correct application of research methods and statistical analysis for specific research undertakings.

Not all researchers will need an extensive knowledge of statistical analysis to present their research, but an awareness of the different methodologies available for analysing research will enable researchers to select the most appropriate methodology to do justice to their work. The objective of such an e-learning module is to enable researchers to keep up to date with changes in approach in the field of statistical analysis and satisfy personal changing needs as each individual researchers work evolves with time. The term e-learning refers to various forms of teaching and learning which are facilitated through the use of technology.

In addition, should a community of practice evolve this may encourage researchers to communicate with other researchers to discuss the most appropriate statistical analysis methods to employ in specific circumstances. "A community thrives not only on its resources, but also on the relationships among its members" (Cheak, Angehrn, & Sloep, 2006, p. 123). Such a community of practice would facilitate students by providing a potential environment to support each other's research efforts. A community of practice is formed when a group of people are drawn together through shared interests or goals. Generally, the members of the community of practice benefit from the sharing of knowledge and experience, and peer support (Dawson, 2010; Sitthiworachart & Joy, 2008). The use of discussion boards are a good medium for facilitating asynchronous online communication between members of the community of practice. E-mail is another example of an asynchronous communication affordance (Smyth, 2011). Web conferencing (Scott, Castañeda, Quick, & Linney, 2009; Smyth, 2011) can be used to facilitate synchronous online communication between members. Hierarchical and peer relationships when used together can promote a rich learning environment (Christiansen & Bell, 2010). An e-learning module would enable researchers to link up with others with similar research interests and perhaps collaborate for writing: journal articles, conference presentations, chapters of books, books or reports.

The benefits to be achieved by providing researchers with an e-leaning module would include: storage of notes, learning activities, and web links, in the one location, the opportunity to form a community of practice, the chance to collaborate with other researchers, and more than likely benefit from the support and guidance of peers.

The background section is broken down into a number of sub-sections: data types; quantitative and qualitative data types; and statistical analysis. This is followed by a section on e-learning module and blended learning which includes sub-sections as follows: community of practice and online collaboration; improving the quality of research; and personalised e-learning. Issues, controversies and problems encountered by researchers are discussed and some solutions and recommendations are made as to how these can be resolved by using an e-learning module. Future research directions are reviewed and the chapter is concluded.

BACKGROUND

The term 'researcher' will be used as a generic term in this chapter to represent any or all of the following who are involved in research: degree, post graduate, masters and PhD students, research fellows, academic researchers, and business researchers.

Researchers' interests tend to evolve as a result of unforeseen contributory factors, for example: funding opportunities, enterprise opportunities, attendance at seminars, research findings, or through the recognition of a specific hypothesis which merits further inquiry. Such influences can force researchers to select alternative research methods and statistical analysis techniques to the ones which they initially envisioned to be most appropriate to their own specific research interests. An e-learning module would enable students to explore different analytical approaches, as the need arises, to satisfy their research requirements as they change with time.

An e-learning module can be used for the: dissemination of course notes; administration of the course; dissemination of assignments; submission of assignments; use of asynchronous and/or synchronous discussions; enabling of students to peer review the submission of other students.

Asynchronous discussions refer to discussions which do not take place in real time. Each subscriber has the opportunity to research and present their opinion to a discussion board for peers to review at some later time. Asynchronous discussions enable subscribers to plan, research, structure, and reflect on their submission before they submit it to the forum for peers to review. Synchronous discussions refer to discussions which take place in real time. Subscribers respond to other subscribers' suggestions and comments without the opportunity to plan, research, structure, and reflect upon their submission to the forum. There are educational merits to both forms of communication.

An e-learning module for researchers would contain educational resources on research methods and statistical analysis to suit a broad range of requirements. Some researchers may already have some knowledge of research methods and statistical analysis while others may be totally new to conducting research. A range of learning activities should be provided in the e-learning module grouped into different levels of difficulty. Therefore enabling researchers to select the activities which best suit their existing level of knowledge and specific requirements at any point in time and work through the resources at their own pace. Skinner (1981) recommends that participants be presented with an alternative sequence of simpler tasks to perform if an initial task is too complex to grasp. By providing tasks aimed at different levels of competence, researchers at all levels should be able to identify and benefit from the use of appropriate e-learning activities.

Competent use of research methods and statistical analysis is paramount to the skill set of researchers. Peer reviewers will soon spot if the methods applied are unsuitable or ill used. Salmon (2009) mentions that statistical analysis is one way of observing trends but statistical analysis methods available for virtual worlds are neither well co-ordinated nor reliable. This statement supports the argument that researchers require a more comprehensive knowledge of statistical analysis methods and techniques and appropriate application to research in order to correctly compile and present findings to ensure their reliability when discussing virtual environments and other research areas.

DATA TYPES

There are two main types of data: quantitative and qualitative. Researchers need to be familiar with both types to ensure that they approach their study with an informed mind to enable them to apply the most appropriate type to test their hypothesis. The combined use of quantitative and qualitative data types facilitates triangulation of data sources enabling researchers to substantiate findings by correlating the hard facts of the numerical quantitative data with the soft more human side of qualitative analysis.

Quantitative and Qualitative Data Types

Quantitative methods of data collection include the collection of numerical data and participants' responses to closed ended questions. Closed ended questions can lead participants to concentrate on specific areas. Qualitative methods of data collection include the use of open ended questions which enable participants to give their views and opinions on issues without any influence from the researcher. Qualitative methods enable researchers to gather personal human experiences relevant to the hypotheses. This gathered data should contain unbiased views on research questions. The findings from both methods can then be correlated to see if they substantiate each other.

Quantitative analysis uses techniques including ratios to analyse numerical data that represent measurable characteristics in order to make sense of available information. Quantitative research tends to be framed in numbers or closed-ended questions, which do not encourage or facilitate the respondent to add any extra information which they feel is relevant. Hence, the opportunity to collect some very worthwhile feedback can be lost. More importantly, the findings of such research could be biased by the researchers own views. Because the researcher may unintentionally set specific boundaries on the information harvested, by leaving respondents no opportunity to divulge other thoughts on the subject. Such data collection methods could influence the conclusions derived from the data and effectively make the research useless.

Quantitative analysis alone produces insufficient in depth knowledge to do justice to the majority of research questions involving complex human experiences. Qualitative analysis is conducted by using techniques such as interviewing and observing participants and the collection of both oral and written communication from participants which can provide improved understanding of complex human experiences. A key consideration is how to improve the quality of researchers use of qualitative research in higher education (Davidson & Jacobs, 2008). Due to the diverse spectrum of influences that affect human lives, researchers require a variety of methodologies and techniques in order to achieve a deeper understanding of human experiences in order to generate useful knowledge as suggested by Fossey, Harvey, McDermott and Davidson (2002). Chesebro and Borisoff (2007) suggests that grounded theory emerges from data from the ground up, qualitative research deduces meaning from words and quantitative research commence with a theory to examine. Creswell (2009) suggests that qualitative analysis is framed using words and open-ended questions, whereas a mixed method approach incorporates elements of both quantitative and qualitative analysis.

Brannen (2005) recommends from empirical evidence that there is strong support for combining both qualitative and quantitative data types in research. Researchers could perhaps benefit from seeing a variety of research methods and the collection of different data types applied to different case studies. An e-learning module which also encompasses standard e-learning functionality such as discussion boards and chat facilities would enable students to discuss with peers their thoughts on the various approaches. Discussion and reflection are very important aspects of the learning experience of students and the investigative work conducted by researchers. The suggested module would enable students and researchers to engage with the e-learning resources and take time to reflect on the information which they have gathered. Subsequently, researchers could discuss their thoughts with peers using the discussion boards, or face to face discussions, to turn this information into knowledge. Such activity would assist researchers in using quantitative and qualitative methods in the most effective way. Hoyles, Küchemann, Healy and Yang (2005) recommend that corroborating evidence gathered through quantitative and qualitative data types used in research methods aids interpretation and contextualization.

Statistical Analysis

The range of statistical methods and techniques is vast and researchers could benefit from an e-learning module that would assist them in identifying the most suitable techniques to apply to their studies. An e-learning module would accommodate researchers' requirements as Murphy (2008) suggests researchers approaches change and statistical analytical requirements evolve throughout the course of their studies. Some statistical analysis techniques in regular use by researchers include: Analysis of variance (ANOVA); Chi-squared test, Correlations, Regression analysis, and Student's t-test.

E-LEARNING MODULE AND BLENDED LEARNING

An electronic learning (e-learning) module facilitates ubiquitous access to learning resources providing the student has broadband connectivity and the necessary computer equipment. Blended learning is where electronic learning resources are used to augment/enhance traditional teaching methods. Akyol and Garrison (2011) suggest high levels of cognition and learning outcomes can be achieved using blended learning. The proposed e-learning module could be used by educators to augment structures already in place to support researchers. Technology enhanced learning (TEL) refers to the support of teaching and learning through the use of technology and can be used synonymously with e-learning, technology enhanced research has the possibility of supporting researchers and perhaps improving the quality of research.

Despite the fact that the merits of technology enhanced learning have yet to be proven teachers are still encouraged to undergo training in the pedagogic use of technology (Jung & Latchem, 2011). Lecturers and teachers are continuously being encouraged to participate in e-learning summer schools, teaching qualifications which involve the use of Information Communication Technology (ICT), and research which also involves a reasonable knowledge of technology. Increasingly interactive whiteboards are being introduced to the classrooms at various different levels of the educational environment. Technology in learning is not going away any time soon, so educators may engage with the use of technology in educating their students, leave technology out of their pedagogic approach if it is deemed unhelpful or continue using technology to enhance the learning experience if they deem it beneficial. The minds of educators need to be informed of the pedagogic benefits which can be realised by using technology in their teaching methodologies, if educators are still not satisfied that technology can have a positive impact on the learning experience then they possibly have the choice of removing the use of technology from the classroom. Some departments and schools embrace the use of technology and encourage educators to create an online presence, others leave it up to the individual educators to decide which teaching methods they wish to employ.

Community of Practice and Online Collaboration

An e-learning module would enable researchers to collaborate with other researchers in order to identify the most appropriate analytical methods to use to evaluate and portray specific data in the most appropriate format. Students online collaboration facilitates a social environment "that promotes better learning" (Doering, Pereira, & Kuechler, 2012, p. 5). Collaboration refers to people working together as a team on a particular project or working together online to achieve a shared goal. "Good interdisciplinary research requires genuine team work and appreciation of the different skills contributed by the partners involved" (Bowman, 2007, p. 361). Unwin (2007) discusses the importance of good communication skills, continual interaction with peers, and "acting with mutual respect and understanding" (Unwin, 2007, p. 355). These interpersonal skills are paramount to the success of a community of practice. Figure 1 illustrates how a community of practice could evolve through the use of an e-learning module.

In addition, such an e-learning module would provide each researcher with access to a well informed community of practice to call upon for support as their research requirements demand. The ubiquitous nature of such a module would have the possibility of enhancing learning experience of researchers. This module could also facilitate researcher collaboration across various disciplines. Such a module could be created to augment and enhance the classroom experience of students as a form of blended learning. During the classroom sessions, students could be encouraged to engage with, and make effective use of the e-learning features. In addition, students should be urged to form a community of practice through the discussion boards and the chat facility. The use of discussion boards in the Masters in Information Systems for Managers (MISM) course (Oscail, 2007), encour-

Figure 1. Community of practice

aged the students to form a community of practice. The community of practice enhanced the learning experience of the students who participated and contributed to the asynchronous and synchronous discussions. Some of the most frequent contributors to the online discussions achieved the most satisfaction from the course. When the Masters in Information Systems for Managers (Oscail, 2007) course ended so did the discussions. Such an e-learning module could be used by students/ researchers to review methods and techniques, and to participate in the community of practice with other researchers to discuss further research projects and to disseminate findings.

Rovai (2002) discusses the importance of establishing a sense of community and hence reducing feelings of isolation. Due to the nature of research, each individual travels a unique path of discovery. This indeed can be a lonely, isolated process. Being afforded the opportunity to engage with other researchers as the need arises to discuss progress, or possibly more importantly: lack of progress, seek advice or generally just to get thoughts straightened out, could help alleviate the feelings of isolation. Moderato (2006) observed that a negative effect of isolation is the lack of exchange of ideas with other researchers. Such an e-learning module would facilitate the exchange of ideas with other researchers. In addition, the theoretical course content in the statistical analysis part of the module could be dipped in an out of as the researchers interests evolve and requirements change.

Vygotsky (2004) in a paper "Imagination and Creativity in Childhood" stated that "Nothing important in life is achieved without a great deal of emotion" (Vygotsky, 2004, p. 55). A PhD qualification is a prestigious achievement in life, a great deal of emotion can be felt by researchers while striving to achieve this goal. An e-learning module such as the one proposed in this chapter, would enable researchers the opportunity to support other researchers going through the research process, as part of a community of researchers the burden of emotional frustrations could be shared with others. Resnick (1987) recommends that researchers may also avail of the opportunity to augment their work by using cognitive tools devised by others. An e-learning module would afford researchers the opportunity to review and discuss the relevance of using tools devised by others to enhance their own research approach. Ribot (1901) recommends that researchers can also augment their work by reviewing anonymous inventions. Researchers need to review the work of others, even if the contributions are anonymous to create a state of the art literature review and position their work in the research area with respect to the achievements and discoveries of others. According to Cole et al. (1978) through Vygotsky's concept of Zone of Proximal Development, researchers would benefit through contact with more capable others or peers for guidance on the most appropriate methodology to use for specific research interests. Researchers using the module could be encouraged to leave contact details with appropriate statistical methods that they have applied in their research, so that other researchers contemplating the use these methods can get in contact. Thus, inexperienced researchers would have the opportunity to discuss their research methods and analytical approaches with others who have been through the PhD process and perhaps benefit from the shared experiences of more capable others.

Piaget (2008) suggested that reasoning develops as a result of trying to argue one's own views on a subject. Participation in such an online community of practice would allow researchers the opportunity to discuss/argue various viewpoints on theories, research methods and techniques used in the research process, in order to establish the approach most suited to the research which they are undertaking. All of the above supported arguments suggest that such an e-learning module would effectively improve the overall quality of PhD research and research in general.

IMPROVING THE QUALITY OF RESEARCH

An e-learning module on research methods and statistical analysis could perhaps improve the quality of the research and also enable researchers to communicate with each other by forming a community of practice to share knowledge and provide support to each other. The content for this module would contain all the theory, methodologies and techniques used in research methods and statistical analysis currently available for researchers to use when planning and analysing their research. Along with appropriate questions, solutions and applied examples to assist researchers in identifying the most appropriate research methods and statistical analysis techniques to apply to their specific research questions. This module would assist researchers in identifying learning content best suited to their needs. Therefore, the learning outcomes to be achieved through engagement with this module will be tailored to the specific needs of each individual researcher's requirements.

In essence, the objective of the proposed e-learning module is to: enhance the learning experience of researchers, improve their research outputs and ensure the peer supports are in place to assist them in completing the process.

Researchers could initially attend introductory courses on research methods and statistical analysis enhanced by proposed e-learning module. Involvement in the module should be encouraged. Researchers can be motivated to engage with each other to create an online community of practice within this module. At the completion of the introductory courses researchers could still have access to this e-learning module to use to refresh their skills as necessary or to delve into other methodologies and techniques as the need arises due to changing research needs. But, most importantly of all, to communicate with other researchers through the community of practice, to benefit from the peer review and help and advice which fellow researchers are willing to share.

Personalised E-Learning

Kalyuga and Sweller (2005) found that learner-adapted formats in e-learning environments proved to be more effective than non-adapted formats for changing levels of learner expertise in a domain. It would be interesting to test whether the provision of learner-adapted formats in a module for researchers would improve their expertise over a module which did not adapt to learners. This approach is based in the area of personalised e-learning. The creation of personalised e-learning formats is a complex process which is not easily achieved by non-technical educators. Dagger, Conlan and Wade (2003) recommend the use of a personalised e-learning module would effectively enable reusability, accessibility, interoperability and durability of peer reviewed learning resources. Access to such a personalised e-learning module would ensure that researchers have access to good quality learning content tailored to support their specific research requirements at all times.

Duncan-Howell (2010) in a paper "Teachers making connections: Online communities as a source of professional learning" suggests "Online communities may present a source of continuous professional development for teachers as they are able to deliver authentic and personalised opportunities for learning" (Duncan-Howell, 2010, p. 324). Online communities do afford learners the opportunity for personalised support from peers. The proposed e-learning module would provide researchers and PhD students with personalised support from their peers, in a timely fashion, which is relevant to their current research undertakings.

ISSUES, CONTROVERSIES, AND PROBLEMS ENCOUNTERED BY RESEARCHERS

Issues

A researcher may seek advice from the online community of practice and be accidentally led astray by a peer. Alternatively, a member of a collaborative team may misinterpret their role within the team and produce work which is outside the scope of the project (Donnelly & O'Rourke, 2007). An exemplary guide on the side would be necessary to ensure that questions posed by researchers to their peers were correctly answered, that each member understood the scope of collaborative projects, and that all contributions were from good quality peer reviewed resources i.e. journal papers, books, book chapters and lecture notes. Edwards, Perry and Janzen (2011) suggest there is a need for strong, positive educators to affirm learners personal worth online and in the classroom. Educators can have an enormous influence on the learning experience of students online and in the classroom; some educators form a better rapport with students than others

A researcher may be aware of the research approach which they believe to be the most appropriate to apply to a specific hypothesis but would like assurance that this is the most appropriate method to apply. A discussion with peers on the merits of the intended approach could help clarify the approach and improve the quality of the research output. This module would also assist researchers who are uncertain of which research method to apply and the type of statistical analysis to use for a specific research question to seek guidance from peers. The guide on the side would monitor the advice to ensure the researcher in need is receiving good advice, discuss online if necessary, so all the other researchers can benefit from the discussion.

The time of lead researchers and PhD supervisors is a valuable asset as they have many and varied responsibilities including for example: Chair of a Board, Member of a Committee, Head of Department, Leading various research projects or lecturing commitments. Therefore, the use of an e-learning module would facilitate the peer review of research contributions before the lead researcher or supervisor need be consulted for guidance.

Asynchronous online discussions can be facilitated through the use of a discussion board. Discussion boards are the ideal tool to use to submit definitions, reviews, figures, tables and citations relevant to various topics to share with fellow students. The use of discussion boards gives students the opportunity to reflect on the submissions of others, conduct research of their own and then post at their leisure when they felt that they had something relevant and worthwhile to contribute. Akyol and Garrison (2011) suggest asynchronous discussions have generated interest amongst educators with respect to deep and meaningful learning. From personal experience of using asynchronous discussions to explore various topics the author's opinion is that educators' interest in further exploring the use of asynchronous discussions in education is justified.

Synchronous discussions can take place through the use of a chat facility. From experience the chat facility for the purpose of conducting synchronous discussions was not a great success. Students participated by typing their contribution to an online conversation. This medium of communication suits some students but not others. Speed typists can contribute very quickly and keep up with the typed conversation. Student participants who were not speed typists find that it takes them so long to type a response that by the time they go to post their contribution to the conversation, the topic of the conversation has moved on leaving their contribution out of synch with the current flow of the online conversation. The synchronous discussion would be better conducted through web conferencing which would enable each student participating in the discussion equal opportunity to contribute to the discussion. Bower, Hedberg and Kuswara (2010) successfully used web-conferencing environments to enable students engage in collaborative design. Dolan, O'Connor, Mullally and Jennings (2004) conducted a study on synchronous e-learning and found "the outcomes were deemed to be very positive" (Dolan et al., 2004, p. 1).

When researchers in the Knowledge and Data Engineering Group (KDEG, 2013), in the School of Computer Science and Statistics, Trinity College Dublin were involved in the GRAPPLE FP7 STREP Funded Project (GRAPPLE, 2008), web conferencing was used to discuss evaluation guidelines (Steiner et al., 2010), training approach (Glahn, Steiner, De Bra, Docq, & O'Donnell, 2010), final evaluation (Glahn et al., 2011) and various other issues which needed to be discussed. The participants in the GRAPPLE project were based in various European universities (GRAPPLE, 2008). The use of web conferencing in this instance reduced: researchers time spent on attending conferences, budgetary expenses, inconvenience to lifestyle, and undue damage to the environment due to travel induced air pollution.

Controversies

Netiquette must be observed at all times. In the case of researchers disagreeing on the appropriate use of techniques, respect must be shown for peers and all arguments must be supported by relevant citations and links to the cited sources. Should researchers disagree on the most appropriate research method to apply to specific research questions, the relevant supervisor(s) or lead researcher's opinion should be sought. Resolution paths may be required to deal with some controversies, for example, round table discussions with an appointed chair to review research positions and directions which may be justifiably challenged.

Problems

From experience using an e-learning module to support students, some students made regular and relevant contributions to the discussion board while others did not personally contribute but regularly followed the comments and work submitted by others. Akyol and Garrison (2011) comment that students were of the opinion that in order for the process to work all parties should contribute equally. Some type of encouragement is required to get all students to contribute to the forum to make it a success. The approach to resolving this issue in both the Masters in Information Systems for Managers (Oscail, 2007) and the Post Graduate Diploma in Business Information Systems (DIT, 2007) was to allocate marks for student contributions to the discussion board as part of the continuous assessment mark. The marking scheme for the student contributions was based on: the relevance of the contributions made and that the contributions were supported by citations from peer reviewed sources.

The success of an e-learning module to support researchers would be dependent on a number of factors such as the: researchers' motivation, supervisors' motivation, and the impact of publications resulting from the researchers' engagement with the e-learning module and so forth. The chosen discipline of each researcher/supervisor will also influence the dissemination rate, citation rate, and the impact factor. Some research areas may only attract the attention of a very small specialised niche group, which will duly affect the citation level and hence the impact factor, though the researcher may be very highly motivated.

"A scientifically written article comprises a reference section at the end where all the references mentioned in the document are cited serially, and each reference is a citation. A citation count is the frequency of an article cited by other articles" (Nigam & Nigam, 2012, p. 511). PhD students and researchers require an awareness of citations counts and their values to enable them target appropriate publications with their research. "Citation counts are often interpreted as proxies for the scientific influence of papers, journals, scholars, and institutions. However, a rigorous and scientifically grounded methodology for a correct use of citation counts is still missing" (Radicchi & Castellano, 2012, p. 1).

Hassad (2010) on discussing "Doctoral education (PhD) in the USA" (Hassad, 2010, p. 1), concludes "it may be an opportune time to explore adopting a PhD education model that is emerging in the European system, and which requires students to produce published peer-reviewed articles instead of (or in addition to) the dissertation" (Hassad, 2010, p. 4). Researchers can realise invaluable feedback from the peer review process. The peer review of many researchers in the same discipline as a PhD student can broaden the student's outlook and improve their approach and academic writing style. Hassad (2010) suggests the model for PhD education which is emerging in the European system would add "another layer of accountability (and quality control) to the process, which can facilitate improved faculty support, and result in better prepared graduates" (Hassad, 2010, p. 4). For PhD students and researchers to know which journals, conferences, and publishing organisations to target with their research output, they would require knowledge of how the publishing process, citation counts, and how the Journal impact factor system works.

Lokker et al. (2012) cites both Garfield (Garfield, 2006) and Thompson Reuters Institute of Scientific Information (ISI, 2012), in the explanation of how Journal impact factors (JIFs) (Garfield, 2006) are calculated in all journals indexed by Thompson Reuters Institute of Scientific Information (ISI) (ISI, 2012), in the following quote on how to calculate JIFs. "Journal impact factors (JIFs) are calculated as the number of times articles in a journal published over a two-year period (e.g., 2005-2006) are cited in all journals indexed by Thompson Reuters Institute of Scientific Information (ISI) during the following year (e.g., 2007), divided by the total number of substantive articles and reviews published in that journal in the first two years (e.g., 2005-2006)" (Lokker et al., 2012, p. 28). Lokker et al. (2012) in the same paper suggests "Ultimately, it would be desirable to use a more robust and less controversial reference standard than JIF, which is based solely on citation counts of a somewhat arbitrary set of articles within journals over a fixed period" (Lokker et al., 2012, p. 32). Ideally, it would be nice to gauge papers by a less controversial reference standard, but this is one of the standards currently used to rate the impact factor of papers.

The h-index is another method in use "An h-index of 20 means that the scientist has published twenty papers that each had at least twenty citations" (Bador & Lafouge, 2011, p. 110). Another ranking method for papers is based on download counts "Journal of Vision (JOV) recently began publishing download counts for every published article. The journal also ranks the top 20 articles by download" (Nigam & Nigam, 2012, p. 512). A combination of the above methods for ranking the impact of papers could be used to determine the success of the e-learning module for researchers. In the meantime, Tous et al. (2011) suggests "Because citation analysis has become a critical component in scholarly impact factor calculation, and considering the relevance of this metric within the scholarly publishing value chain, we defend that the relevance of providing a reliable solution justifies the effort of introducing technological changes within the publishing lifecycle" (Tous et al., 2011, p. 33).

Granić and Ćukušić (2011) suggest that the poor design of e-learning systems are one of the contributory factors to the slow uptake of e-learning. Another is the fear of appearing unprofessional (O'Donnell, 2008) or incompetent should the technology fail. Lack of time to engage with e-learning training and to create e-learning modules (O'Donnell, 2008) is another reason why educators do not engage with e-learning. The creation of e-learning modules takes considerable expertise (Thompson, Jeffries, & Topping, 2010). Above are just some of the reasons why educators do not employ the use of e-learning modules.

SOLUTIONS AND RECOMMENDATIONS

An exemplary, strong and positive guide on the side familiar with research methods and statistical analysis should be available to oversee the use of the e-learning module for researchers to ensure the methods and techniques are correctly applied. The guide on the side would be responsible for ensuring that netiquette is observed at all times by researchers using the module.

Identifying suitable units of learning to present to students is a skill or problem solving process which educators continuously strive to improve. By providing researchers with a range of units of learning to facilitate self directed learning this would transfer the problem solving process to the researcher who then has the responsibility of identifying the most appropriate units of learning to study by themselves and apply to their research. This module would afford learners the opportunity to participate in different learning experiences based around a single concept in an attempt to broaden their knowledge of research methods and deepen their understanding of underlying concepts.

Examples of various different approaches to conducting research could be provided to enable students to obtain a better understanding of the complete research process from different perspectives. A comprehensive understanding of the research process and how and where to get published would assist students who are starting out on the path of discovery. The concepts depicted in the following figures are basic starting points; other concepts can be added to the various sections of the e-learning module at any stage. The concepts listed in the following figures are not exhaustive. Figure 2 portrays a simple example of how a researcher would approach testing a hypothesis through to dissemination of research findings.

Researchers would review various different approaches in order to identify the approach best suited to their particular research requirements. Researchers could use the e-learning module to discuss the different approaches with their peers through asynchronous or synchronous discussion to assist them in identifying the most appropriate approach to use for a particular type of research. The target media for dissemination of research will dictate: the rigour of analysis required, the referencing style to be used, and the preferred word processing formats.

Figure 3 outlines a selection of learning resources suitable for use by a researcher when commencing testing a hypothesis. Initially, the researcher would be led through a scenario outlining how to conduct a state of the art literary review.

Figure 2. Testing a hypothesis through to dissemination of findings

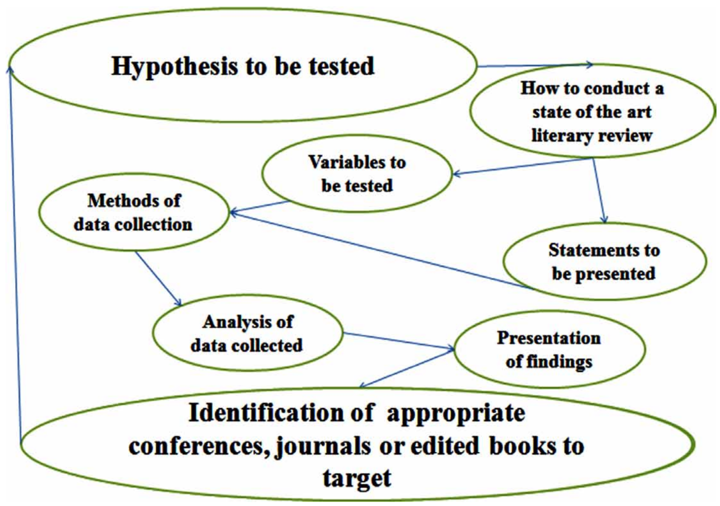

Figure 3. Resources to review

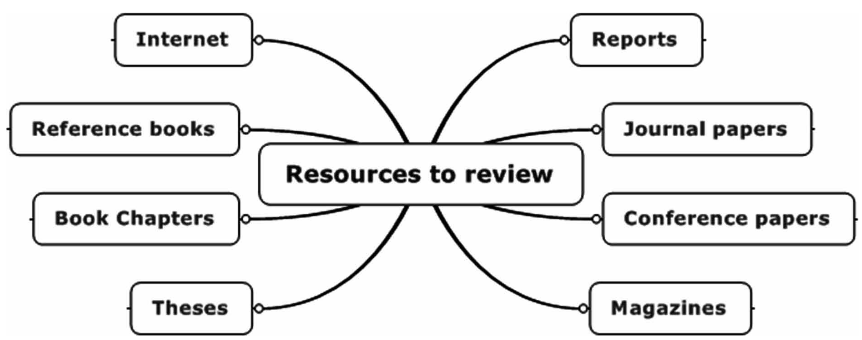

From the state of the art survey conducted the researcher would identify a set of variable to be tested to obtain quantitative data, and statements/ questions to be presented to participants to obtain qualitative data to analyse. Once the researcher has identified variables and statements to be tested, the most appropriate research methodology must be applied. The students should then consider the research methods options available for collecting data, as outlined in Figure 4.

Research ethical clearance must be sought and granted before commencement of data collection, regardless of the methods of data collection selected. Guidance on how to apply for research ethical clearance should be provided for students within the e-learning module. Templates to apply for research ethical clearance should be made available and updated as the need arises. Samples of applications for research ethical clearance which have previously been granted should be available; to assist researchers and PhD students in the process of obtaining research ethical clearance.

The researcher then has to decide on the format of the data to be collected. The researcher has to consider in advance how they are going to analyse the collected data. The data can be collected in numerous different formats as indicated in Figure 5.

Options to consider when performing the analysis of data collected would be provided as per Figure 6. These options would be expanded upon within the e-learning module, to enable the PhD students and researchers read up on the

Figure 4. Methods of data collection

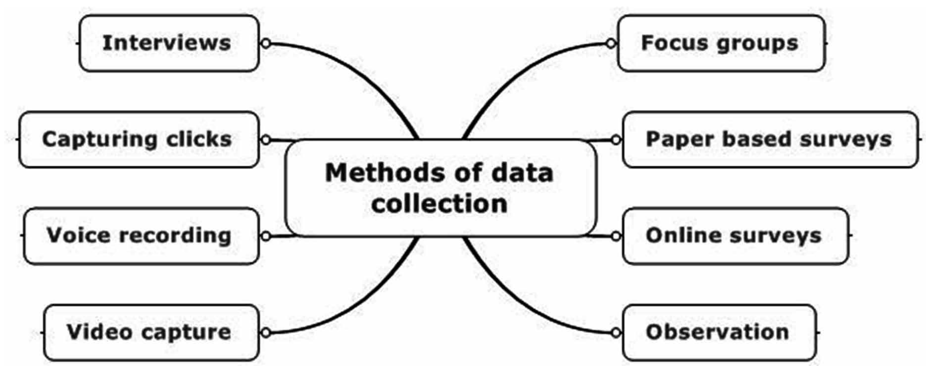

Figure 5. Format for data collection

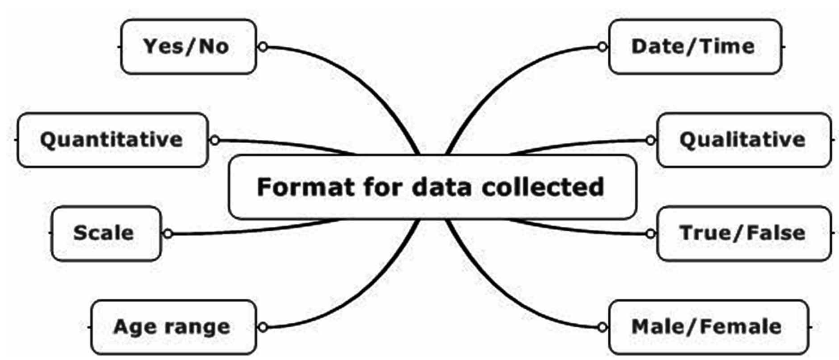

various options available and select the option(s) most suited to the specific research they are currently pursuing.

In the analysis of data collected section, the e-learning module would enable researchers to select the most appropriate methods of data analysis relevant to the type and volume of data collected.

The presentation of findings may well depend on the discipline and where the research is to be published. Some publishers prefer black and white submission, for example, reference books, whereas, posters are generally in colour. The presentation of the findings will depend on the type of publication targeted. The e-learning module would supply information relevant to the type of publication targeted, for example:

- Summarised version for a poster
- 4,000 words for a journal article
- 8,000 – 10,000 words for a chapter of a book

Researchers should be advised to keep their formatting to a minimum in their initial draft of findings, then it is easier to insert into templates for book chapters, conference submissions and so forth, as the need arises. Figure 7 portrays the various different publishing opportunities for researchers.

Depending on work and personal commitments, different publishing venues will suit different researchers' lifestyles. Due to timetabling of contact hours lecturers may find it difficult to commit to attending conferences during term time.

Figure 6. Analysis of data collected

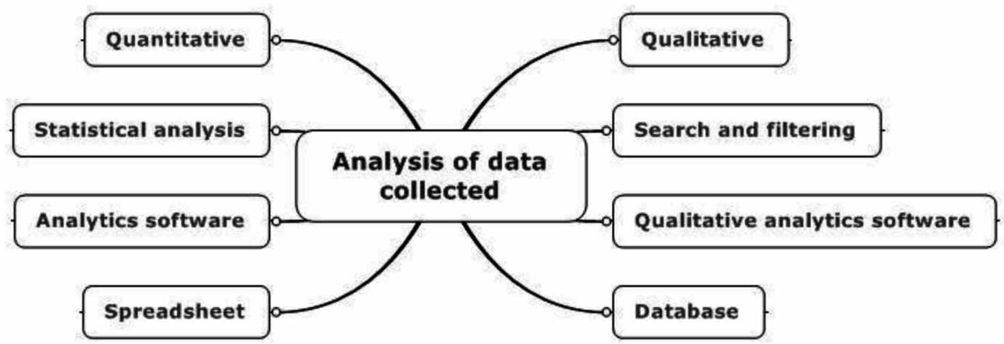

Figure 7. Where to publish

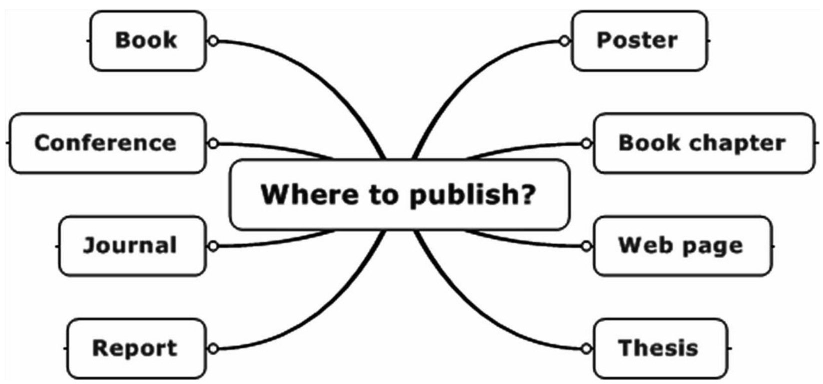


Presenting at conferences may gain the researcher some acknowledgement from the conference attendees, but an article in an electronic journal or an electronic book (e-book) may be more easily accessible to many. The e-learning module could outline the content relevant to publishing in each of these different venues and highlight the advantages and disadvantages of each.

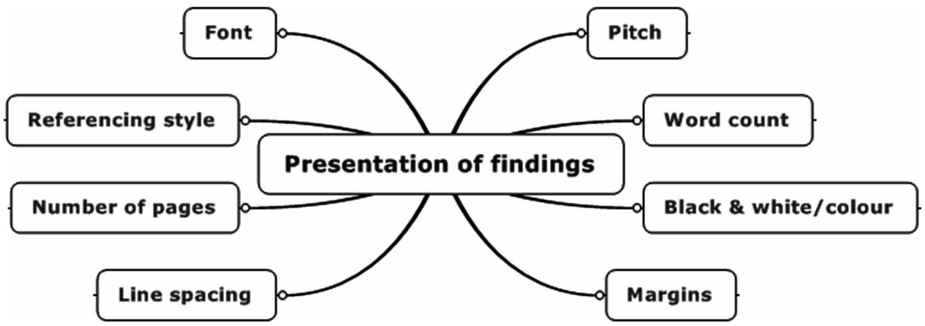
The presentation of findings or dissemination of research will be dependent on the publication type selected. Different publishers require different publishing formats and different referencing styles. As previously mentioned, it is advisable when collating results to keep the applied formatting to a minimum, then the text, tables and figures can easily be inserted into the formatting required by the publisher. Some publishers will not consider papers unless they are submitted in the correct format and citations follow the required referencing style. Figure 8 indicates some formatting issues; the requirements will differ depending on the publisher.

The combined e-learning module would conceptually appear as a combination of all the figures used in this chapter. The use of discussion boards, synchronously and asynchronously, would assist researchers understanding and use of these concepts.

FUTURE RESEARCH DIRECTIONS

To investigate if the proposed e-learning module would improve the quantity and quality of research publications, one method would be to compare the quantity and quality of the research

Figure 8. Presentation of findings



output of researchers who have engaged with the published research output of students who have not engaged with an e-learning module. An alternative method would be to create such an e-learning module, encourage student engagement, gather student feedback and analyse the feedback to see if the creation and implementation of such a module would be perceived as beneficial to researchers. Should either of the above solutions for the proposed module be pursued, the findings will provide a good indication as to whether such an e-learning module would improve the quality of research undertaken by PhD students and researchers. The process of evaluating such an e-learning module requires further research which promises to be an interesting study. Engagement with such an e-learning module has the potential to improve the quality of research and the quantity of research publications by facilitating online peer support. Furthermore, by adding some adaptive functionality to the e-learning module students could perhaps benefit from personalised e-learning whereby learning objects would be selected by the system to suit individual students learning needs.

CONCLUSION

This purpose of this chapter was to propose the use of an e-learning module to support researchers to improve the quality of research and increase research dissemination. An e-learning module on research methods and statistical analysis would perhaps improve the quality of research by providing students with the necessary skill set to identify the most appropriate research methods and statistical analysis to apply to their research. Thus, enabling students to effectively conduct research and subsequently analyse, interpret and contextualise the findings. In addition, the quality of research would perhaps improve as a result of the peer reviewed feedback received from the other researchers involved in the online community of practice. Opportunities for collaborative work would also be identified through discussions on research interests and approaches. Collaborative work on papers, book chapters and conference submission could increase the research output of the researchers and research groups who actively engage with an e-learning module to support researchers in higher education.

KEY TERMS AND DEFINITIONS

Asynchronous Discussion: Refers to discussions which do not take place in real time. Each subscriber has the opportunity to research and present their opinion to a discussion board for peers to review at some later time. Asynchronous discussions enable subscribers to plan, research, structure, and reflect on their submission before they submit it to the forum for peers to review.

Blended Learning: Occurs when electronic learning resources are used to augment/enhance traditional teaching methods.

Community of Practice: Is formed when a group of people are drawn together through shared interests or goals.

E-Learning: Refers to various forms of teaching and learning which are facilitated through the use of technology.

E-Learning Module: Is stored in a predefined location on an e-learning platform and is dedicated to a particular subject area. Students are provided with user names and passwords to access and contribute to this module. Because the e-learning module is online, students can access this module at any time from any place, providing they have the appropriate computer equipment and broadband access.

Online Collaboration: Refers to people working together online to achieve a shared goal.

Qualitative Analysis: Qualitative methods facilitate the use of open ended questions which enable participants to give their views and opinions on issues without any influence from the researcher.

Quantitative Analysis: The use of techniques including ratios to analyse numerical data which represent measurable characteristics in order to make sense of available information.

Synchronous Discussion: Synchronous discussions refer to discussions which take place in real time. Subscribers respond to other subscribers' suggestions and comments without the opportunity to plan, research, structure, and reflect upon their submission to the forum.

Technology Enhanced Learning (TEL): Technology enhanced learning (TEL) refers to the support of teaching and learning through the use of technology and can be used synonymously with e-learning.

Technology Enhanced Research: Technology enhanced research has the possibility of supporting researchers through the use of technology and perhaps improving the quality of research.

Section 2
Tools and Technologies

This section presents an extensive coverage of various tools and technologies available in the field of Curriculum Design and Classroom Management that practitioners and academicians alike can utilize to develop different techniques. These chapters enlighten readers about fundamental research on the many tools facilitating the burgeoning field of Curriculum Design and Classroom Management. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of Curriculum Design and Classroom Management. With 13 chapters, this section offers a broad treatment of some of the many tools and technologies within the Curriculum Design and Classroom Management field.

Chapter 15
A Quest about eQuest and Blended Learning in Teacher Education: An Indian Study

A. Sivasankar
SASTRA University, India

K. Mohanasundaram
Government Arts College (Autonomous), India

ABSTRACT

While alternate modes of delivery in education are assuming importance, it is imperative to train the pre service teachers to use the web resources to maximise learning experience. This paper attempts to study the inquisitive nature of student teachers of south India to use the e resources named as e quest. This experimental study uses blended learning strategy as a treatment for experimental group and conventional method of teaching for control group with respect to some personal variables. The findings prove that blended learning strategy increases the e quest score of pre service teachers irrespective of their prior exposure.

OVERVIEW

Information and communication technologies (ICTs) are a major factor in shaping the new global economy and producing rapid changes in society. Within the past decade, the new ICT tools have fundamentally changed the way people communicate and do business. (Information and Communication Technologies in Teacher Education UNESCO Planning guide, 2002)

DOI: 10.4018/978-1-4666-8246-7.ch015

With the rapid progress of scientific and technological development, technology of education has also transformed accordingly. Internet has gained the limelight in providing any kind of information on any branch of study. The printed resources had been out moded by electronic resources in terms of creating, hosting, accessing and cost of production. The active seekers of knowledge through internet are increasing exponentially. Instead of totally depending on the instructions imparted by the teachers and the subject matter available in the printed media, the e learners can access the repot ire of information over the internet not only to seek information but also to form groups with interested peer members, to make threaded discussions and to form on line communities the way it happens in the real classroom environment.

Though e learning may be understood as an innovative technique or a form of ICT used in providing learning experiences to the learners through on line by using internet services and web technology, in real life situations it is not limited to internet and web technology alone. Therefore e learning in present day context may be considered as learning carried out, supported and facilitated by the advanced multimedia utilities as well as internet and web technology delivered to the end users in their computers, laptops and personal digital assistants. E learning may be in general classified into total e learning, support e learning and blended learning. In blended learning attempts are made for making use of a combination of traditional and ICT enhanced e learning practices. Blended learning describes the learning environment that either combines teaching methods, delivery methods, media formats or mixture of all these. It also refers to the integrated learning activities such as mixture of on line, off line and face to face learning. In other words blended learning is a mixture of traditional and e learning strategies. It is the combination of face to face learning with web based on line approaches the combination of media, methods and pedagogical approaches, to enhance control over learning, critical thinking and assessment.

In order to perpetuate the organized system of society, teacher education moulds the suitable persons as expected by the society to nurture the young minds as teachers. The strength of an educational system largely depends on the quality of its teachers. Whatever high the aims, however up to date the equipments, however efficient the administration, the performance of children is determined by the teachers. It is high time that we develop a class of teachers who are academically well prepared, trained professionally and can sustain the formidable task of nation building with confidence. These teachers must also posses experimental attitude with wholesome philosophy of education which calls for innovative approaches to prepare teachers at all levels. These teachers must be able to comprehend with findings of educational research, translate them into practice, and feed the same to the up coming generation for further research and development. The prospective teacher must be made to realize his duties and responsibilities in an emerging society like India. He must be taught what is relevant to the needs of the society. The teacher education program should be competent enough to inculcate the qualities, abilities, attitudes, ideals etc…..expected out of good teacher along with the ability to grab and refine the repot ire of information available in the World Wide Web, to scaffold the knowledge base of the learner instantly.

Educational machinery across the world is under severe pressure to use new Information and Communication Technologies (ICTs) to teach learners the knowledge, attitude and skills that are needed for the 21st century. With the help of emerging new technologies the teaching profession is evolving from teacher centric chalk and talk lecture based instruction to student centric, information rich interactive learning environments. Designing and implementing successful ICT enabled teacher education programs is the key to fundamental and wide ranging educational reforms. It is the universal truth that a teacher can not be substituted by any electronic gadget. Many times the newer gadgets are playing a supplementary role along with the teacher's aim of maximizing the learning experiences. In this context the teacher can be said well informed and fully competent only when he is well versed with the usage of web resources and optimal use of them in the required proposition along with his sturdy commitment to discharge his lively role.

Many countries are engaged in a number of efforts to effect changes in the teaching learning process to prepare students for information and technology based society. ICTs may provide an array of powerful tools that may help in transforming the present isolated, teacher centric and text-bound class rooms into rich, student focused, and interactive knowledge environments. To accomplish this goal, it requires both a change in the traditional view of the learning process and an understanding of how the new digital technologies can create new learning environments in which the students are able to take greater responsibility for their own learning and for constructing their own knowledge.

Blended learning strategy can maximize the learning experience with the minimum utilization of resources. It can promote relearning in terms of drill and practice without space constraint. Through blended learning strategy educational cost becomes cheaper, and that makes it cost benefit and cost effective. Storage, preservation of content and timely retrieval of them is easy in blended learning. In case of non formal education it is the powerful medium and can very well replace class room teaching and books as it can provide content with media and animation to promote modernization of education. Blended learning strategy will be more entertaining and encouraging to the students of all age group. If it is employed appropriately the positive attitude towards education can be fostered among young learners which will make learning with out burden a reality. When the ignited learners acquire unquenchable thirst for knowledge, then mastery of learning will be achieved easily. Blended learning strategy can address two important expectations of policy makers namely learning with out burden and mastery of learning. All can be a reality only when we generate a group of passionate teachers who have the real urge in them to better serve the younger generation with the help of net resources. As the urge may be attributed to various factors, the influence and addictive proportions of the e resources collectively termed as e quest which makes the individuals to plunge into the internet again and again. Invariably blended learning strategies may trigger the taste buds of prospective teachers and make them use it as their regular teaching aid. The possible effects of blended learning strategy on e quest need to be assessed, this paper attempts to study the e quest of the pre service teachers in southern part of India through an experimental study using blended learning strategy as treatment.

Objectives of the Study

1. To measure the e quest scores of student teachers.
2. To study whether blended learning environment increases e quest scores.
3. To assess the e quest scores with reference to few personal variables.

Variables of the Study

The independent variable of this study is the blended learning strategy. The dependent variable is e quest scores of student teachers. Other personal variables involved in this study are gender, generation of graduation, and surfing habit.

Hypotheses of the Study

1. There is no significant difference in the post test e quest scores between the control and experimental group student teachers.
2. There is no significant difference in the post test e quest scores between the control and experimental group men student teachers.
3. There is no significant difference in the post test e quest scores between the control and experimental group women student teachers.
4. There is no significant difference in the post test e quest scores between the control and experimental group first generation graduate student teachers.

5. There is no significant difference in the post test e quest scores between the control and experimental group second generation graduate student teachers.
6. There is no significant difference in the post test e quest scores between the control and experimental group student teachers who are surfing regularly.
7. There is no significant difference in the post test e quest scores between the control and experimental group student teachers who are not surfing regularly.

Method

To study the e quest of student teachers the Pre-test, Treatment, Post-test equivalent group experimental design was adopted in the study.

Sample

A sample of 40 B.Ed student teachers each comprising Physical science, Biological science and Computer science optional subjects were selected for the study from a private College of Education and SASTRA University, Kumbakonam a semi urban area of south India as the control and experimental group respectively. They were selected through purposive sampling technique.

Tool of the Study

e Quest scale constructed and validated by the investigator was the tool used.

Research Procedure

The student teachers studying B.Ed in school of education, SASTRA University, Kumbakonam were treated as experimental group, and the student teachers studying B.Ed in a private College of Education, Kumbakonam were treated as control group. Initially the scores secured by the students in their degree examination were analysed. Fifty students from each institution who secured an average range of marks were selected. Then an intelligence test of g culture fair scale 2, form B prepared by R.B. Cattel and K.S Cattel was administered to these students. Then forty students were selected for each control and experimental group with matched pair. Both groups were formed with gender, generation of graduation and other variables of the study. The blended learning environment was created with face to face instruction sessions followed by asynchronous on line sessions comprising word documents, slide shows, audio and video clippings already uploaded through blogs. The online testing tools were also the part of the strategy along with off line media for experimental group and traditional method for control group for a period of six weeks.

e Quest Scale

The act of searching gives the rays of hope for learning. World Wide Web is a place where seekers and learners alike bonded together in search for knowledge. The unquenchable thirst of learning mass in search of information in the electronic media has been termed as e quest by the investigator. What for the individuals are searching or what skill that they feel will improve over browsing have been collectively named as e quest. The investigator intended to study the influence of blended learning strategy over e quest and to measure the relation ship. e Quest was assessed by using e quest scale constructed by the investigator. There are various factors which make the individual to surf in the net. The investigator had identified ten such factors as ten dimensions of the tool and the test contains 50 statements with five point scale. These 50 statements in e quest scale with five point Likert type was assigned a weight age ranging from 4 (strongly agree) to 0 (strongly disagree). For each student a total score in the scale can be obtained by summating his score for the individual items. Thus a range of 0-200 scores can be obtained.

The test items were generated based on opportunity to learn, ability to understand, chances for collaborative learning, Meta cognitive skills and social learning. This scale had been developed to assess the inner urge of the teachers to utilize the internet revolution in their teaching learning process, It is also intended to evaluate any change in the e quest score of student teachers after blended learning strategy.

TEN DIMENSIONS OF eQUEST

Content

Content refers to enormous amount of digital content that can be transmitted over a computer network such as internet. It includes text, audio, video, graphics, animation and so on. Many seekers enter the web in anticipation that their search will end with internet.

Performance

Performance refers to the ability to carry out or the act of execution or sense of accomplishment or achievement. Those who assume that their performance increases through e media favour the dimension performance.

Simulation

The act or an instance of simulating with the assumption of false appearance, form or sequence is simulation. Facing the representation of a problem situation in order to estimate its characteristics or solve problem is simulation. Those who prefer a feign experience or an act of fictious assumption prefer this dimension.

Multi Tasking

Multi tasking refers to the ability of an individual to perform more than one task or many tasks at the given time. In the field of human resource development multi tasking is an important term that is used to describe how busy managers or academic administrators are able to accomplish a challenging amount of work in a given time period. e learner must also posses such multi tasking abilities to grab more.

Collective Intelligence

Collective intelligence refers to shared or group intelligence that emerges from the collaboration and competition of many individuals and appears to be essential for decision making. In order to allow relatively large number of people to co operate in one process leading to a reliable action.

Judgment

Judgment refers to the cognitive process of reaching a decision or drawing conclusions. The ability of an individual to assess situations or circumstances meticulously and to make meaningful conclusions. An opinion formed by judging something seems to be essential for new age learning.

Cross Media Navigation

Cross media navigation is the advantage that the end users are getting by means of navigating from high reach base medium to interactive target media as one can switch from text to graphics then to animated and virtual media where the switch is attractive, rich in information and interaction.

Cyber Relationship

Cyber relationship means a relationship that either was generated or continued solely through the internet as a medium for meeting or communication. The relationship anonymously connect people to share experiences, get feedback, give comment, meet new friends and board in discussion forum.

Group Dynamics

Group dynamics refers to the underlying features of group behaviour such as motives and attitudes. It is concerned with the flexibility in thinking rather than stability in thinking. The interactive process with in the group about the changing patterns of tension, conflict, adjustment and cohesion.

Research Aptitude

Research aptitude refers to an innately acquired or learned or developed component of a competency to do a kind of research work at certain level. Research aptitude represents knowledge or ability that is gained through the internet learning environment.

Expert Opinion

The test items constructed were subjected to jury's opinion consisting of research supervisor, two principals of colleges of education and four experienced teacher educators. The jury's were requested to review each item and its validity with reference to the objectives, appropriateness and suitability to B.Ed students. The suggestions given by them were incorporated to finalize the test items.

Pilot Study

The refined test items were administered to a sample of 25 students. The test items total correlation of each item was computed. The 50 items with significant 'r' values were selected and included in the final test.

Reliability

The reliability of the test was established by test re-test method. The test was administered after a gap of three weeks to 25 student teachers. The co efficient of correlation between the two set of scores was found to be 0.81. The reliability of the test was established by using split half method also. The co- efficient of correlation between the scores of the odd and even items was calculated for 25 students. Split half reliability was found to be 0.76 and using Spearman- Brown formula for the full length of the test 'r' was estimated to be 0.78. Thus the e quest scale for blended learning strategy possesses adequate reliability.

Validity

The content validity was established by the experts and construct validity was established by the investigator, which is 0.82 for e quest. The test items were constructed based on opportunity to learn, ability to understand, chances for collaborative learning, Meta cognitive skills and social learning. Therefore the test possesses content, construct and face validity. This establishes the validity of the tool.

Analysis and Inferences

Hypothesis 1: There is no significant difference in the post test e quest scores between the control and experimental group student teachers. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group student teachers in their e quest scores. The experimental group student teachers are at a higher level than the control group student teachers in their e quest scores (Table 1).

Hypothesis 2: There is no significant difference in the post test e quest scores between the control and experimental group men student teachers. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group men student teachers in their e quest scores. The experimental group men student teachers are at a higher level than the control group men student teachers in their e quest scores.

Hypothesis 3: There is no significant difference in the post test e quest scores between the control and experimental group women student teachers. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group women student teachers in their e quest scores. The experimental group women student teachers are at a higher level than the control group women student teachers in their e quest scores.

Hypothesis 4: There is no significant difference in the post test e quest scores between the control and experimental group first generation graduate student teachers. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group first generation graduate student teachers in their e quest scores. The first generation graduate student teachers of experimental group are at a higher level than the first generation graduate student teachers of control group in their e quest scores.

Hypothesis 5: There is no significant difference in the post test e quest scores between the control and experimental group second generation graduate student teachers. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group second generation graduate student teachers in their e quest scores. The second generation graduate student teachers of experimental group are at a higher level than the second generation graduate student teachers of control group in their e quest scores.

Hypothesis 6: There is no significant difference in the post test e quest scores between the control and experimental group student teachers who are surfing regularly. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group student teachers who are surfing regularly in their e quest scores. The experimental group student teachers who are surfing regularly are at a higher level than the control group student teachers who are surfing regularly in their e quest scores.

Hypothesis 7: There is no significant difference in the post test e quest scores between the control and experimental group student teachers who are not surfing regularly. The calculated value of't' is significant at 0.01 level of significance. This makes it obligatory to reject the above said null hypothesis. It is concluded that there is significant difference between the experimental and control group student teachers who are not surfing regularly in their e quest scores. The experimental group student teachers who are not surfing regularly are at a higher level than the control group student teachers who are not surfing regularly in their e quest scores.

Effect Size Analysis

Effect size analysis was carried out using pooled standard deviation to find out the relative effectiveness of the blended learning strategy over the conventional method. Effect size was 0.8864 and Cohen's d was 3.83 both are relatively large for the achievement of the student teachers in e quest scores as shown in Table 1 and Table 2.

Table 1. Comparison of e quest scores

Variable	Group	N	Mean	S.D	t Value	p Value
e Quest	**Control**	**40**	**64.27**	**22.74**	**17.132****	**0.000**
	Experimental	**40**	**141.82**	**17.39**		
Men	**Control**	**19**	**53.37**	**15.71**	**16.655****	**0.000**
	Experimental	**23**	**141.25**	**18.02**		
Women	**Control**	**21**	**67.00**	**23.60**	**10.879****	**0.000**
	Experimental	**19**	**141.96**	**17.53**		
First Generation	**Control**	**23**	**65.25**	**23.35**	**12.324****	**0.000**
	Experimental	**20**	**139.96**	**14.73**		
Second Generation	**Control**	**17**	**62.23**	**22.20**	**11.272****	**0.000**
	Experimental	**20**	**146.72**	**23.15**		
Surfing Regularly	**Control**	**22**	**62.81**	**19.04**	**14.433****	**0.000**
	Experimental	**21**	**141.81**	**16.71**		
Surfing not Regularly	**Control**	**18**	**65.25**	**25.26**	**10.626****	**0.000**
	Experimental	**19**	**141.83**	**18.19**		

** Significant at 0.01 level

Table 2. Cohen's 'd' and effect size for the variable of the study

Variable of the Study	Mean Scores		Pooled SD	Cohen's 'd'	Effect size	Effect
	Cont.	Exp.				
eQuest	64.27	141.82	20.24	3.83	0.8864	large

Gain Score Analysis

Gain score analysis was carried out to find out the relative effectiveness of the blended learning strategy over the conventional method. The instructional objectives were same for the pre-test and post-test. The gain scores are as much as 56.94 is the convincing proof for the effectiveness of blended learning strategy in improving the achievement of the student teachers in e quest scores. The mean gain and gain percentage are shown in Table 3.

Case Study 1

Among the experimental group subjects the topper is a woman student teacher a mother of two children and aged about 33 years. Her husband is an officer in the army about thousand and five hundred kilometres away from the family. Leaving the two children in her parent's home she pursued her studies. In a personal interview she expressed better satisfaction with this blended learning strategy and rated superior over the conventional method of teaching. She reported that face to face component was very much useful and reiterated that in skill driven topics like micro teaching face to face sessions are vital. Reacting to the question about her confidence about handling the net resources, she expressed her fullest satisfaction over the approach and revealed that so far she never communicated with her husband through internet enabled services and only after this exposure she is doing so. She also reported that cross media navigation was the phenomenon that kept up her

Table 3. Gain score analysis

Group	Samples	Mean Gain	Gain Percentage
Control Group	40	37.37	18.69
Experimental Group	40	113.87	**56.94**

inquisitive nature to go on and on. According to her the total way in which she looks the world had changed with the positive mind set and stands testimony to the fact that blended learning strategy improves e quest of the learners.

Case Study 2

Another subject a twenty one year old woman student teacher from a rural background and not even having a mobile phone expressed better satisfaction after the blended learning strategy and stated that the e media always enhanced the thrill of learning and helped to bridge the cognitive gap between the men and material. She gave equal importance to the face to face components as well as on and off line components of the strategy. She attributed that her search for new knowledge had increased manifold like that of multitasking skills the dimensions of e quest

The above case studies confirm that the blended learning strategy is effective, interesting, offers better satisfaction to the learners and most important that it makes the learners active seekers of knowledge through e media that is e quest.

Discussions

The influence of online e-resources available for learning is inevitable in the global educational scenario. The alternate modes of delivery in education have been upgraded or advanced with the aid of computer and internet in many ways from traditional methods to modern methods. It matches well with Kathleen Gray and Jacinta Tobin (2010) study on clinical education which reports that introduction of online communities produced high student ratings on its quality about teaching and learning. It also produced academic results equal in that of face to face teaching.

Melek Yaman Dittmar Graf (2010) out of the study on International blended learning co-operation project in Biology teacher education had reported that overall the concept of blended learning received relatively high ratings. Mustafa Caner (2010) is of opinion that blended learning environment for teaching practice course could improve the teaching practice and ensure to the professional growth of student teachers.

Technological advancements like e-learning, mobile –learning, web based learning and blended learning would increase curiosity, enhance imagination, problem solving ability and analytical thinking capacity there by augment the research and development of next generation to newer heights. The study of Serap Samsa (2010) with pre-service teachers on scenario based blended learning environment revealed that the pre-service teacher satisfaction was significant over the conventional method.

But in many of the third world countries it seems to be a distant reality due to economy. In spite of the fact in countries like Botswana the blended learning solution attempted by Bopelo Boitshwanelo (2009) on teacher education high lights that, teacher educators should use blended methods and should develop good models for ICT practices, the author also suggests that, drastic changes in the culture of teaching are needed and to adopt situated, participatory and collaborative approaches. This reflects the fact that the thirst for newer educational media is a universal phenomena irrespective of economy and development.

In their study on teacher preparation with technology enhanced learning Hui- Wen Huang and Rodney McConnell (2009) students have in fact appreciated the educational benefits in the combination of online discussion with face to face discussion during their blended approach; they also reported that there is a change in their normal classroom roles from being passive to more active than earlier that is in favour of the dimension of e quest.

Mei –Ya Liang and Curtis J.Bonk (2009) investigated the principle and practices of blended learning for teaching English as a foreign language by applying the concept of interaction to the challenge of creating blended curriculum with textual, social and technological dimensions of interaction. They suggest that interaction driven approach should be the focal point of future development and implementation of blended learning strategies. Similarly this study underlines the preference of interaction by student teachers which will be long lasting.

This attempt of study is to encourage the teachers to use low cost and no cost web resources to enhance learning experience. This study records e quest of pre service teachers who are going to nurture the next generation learners and therefore it is essential to measure their e quest score. It is found that irrespective of personal variables the experimental group that received the treatment through blended learning strategy had got significant higher e quest score over their control group counterpart who received traditional method of instruction. It is attributed to the inbuilt components of blended learning strategy that would have imbibed the thirst in the learners of the group.

CONCLUSION

The instructional effects of blended learning as a strategy may be related to better achievement of the student teachers, where as the nurturant effects may be related to e quest. The instructional effects are immediate and cognitive in nature where as nurturant effects are long lasting and affective in nature. Once we ignite the passion of budding teachers the effect will be a chain reaction.

Ramos – Elizondo A.I and others (2010) study on developing cognitive skills through mobile learning revealed that m learning changed any environment into a collaborative and innovative environment. It also suggests that m learning resources must be based on educational theories and strategies to be effective. It also promotes cognitive skills such as problem solving, decision making, critical thinking, creative thinking and melioration. So making the right blend and making the learners as starvers of knowledge lies with the policy makers.

India has been ranked 69th among 142 nations in inherent capacity to leverage information and communication technologies (ICT) for progress, in the year 2012 issue of Networked Readiness Index report brought out annually by the world economic forum and the business school, INSEAD. It ranked India 48th in the year 2011, against 43rd the previous year. Providing the right ambit for the new generation learners seems to be crucial to face the challenges of digital age learning.

From the above findings of the study it is inferred that blended learning strategy in teacher education will significantly increase the e quest of student teachers irrespective of the gender, generation of graduation and surfing habit. This in turn will create life long learners and long lasting effects on the community.

Teacher education is the grass root of any nation's development and hence it is concluded that innovative teaching strategies like e learning, web based classroom and blended learning will augment the necessary skills that are needed for new age teaching.

ABSTRACT

Blended Learning is a learning model that is enriched with traditional learning methods and online education materials. Integration of face-to-face and online learning with blending learning can enhance the learning experience and optimize seat time. In this chapter, the authors present the teaching of an Algorithm and Programming course in Computer Engineering Education via an artificial intelligence-supported blended learning approach. Since 2011, Computer Engineering education in Suleyman Demirel University Computer Engineering Department is taught with a blended learning method. Blended learning is achieved through a Learning Management System (LMS) by using distance education technology. The LMS is comprised of course materials supported with flash animations, student records, user roles, and evaluation systems such as surveys and quizzes that meet SCORM standards. In this chapter, the related education process has been supported with an intelligent program, which is based on teaching C programming language. In this way, it has been aimed to improve educational processes within the related course and the education approach in the department. The blended learning approach has been evaluated by the authors, and the obtained results show that the introduced artificial intelligence-supported blended learning education program enables both teachers and students to experience better educational processes.

DOI: 10.4018/978-1-4666-8246-7.ch016

INTRODUCTION

Blended learning has various definitions in literature. In a study by Finn *et al.* (2004), C. Procter *et al.* (2003), it is defined as the combination of best features of traditional learning and online learning. However, the definition has evolved to encompass combinations of various learning strategies such as blending offline and online learning, blending structured and unstructured learning etc. Singh *et al.* (2003), Lotrecchiano *et al.* (2013). The goal is to combine the best parts of face-to-face education and online education. Students engage in interactive experiences. Additionally, the online courses provide students with rich multimedia content at anytime, anywhere with Internet access from university or home. This increases the scheduling flexibility of students. There are many ways of applying blended learning. Therefore there are no certain rules to define what the ideal blend might be. The term "blended" has a broad meaning and it includes the integration of e-learning and traditional face-to-face learning. The blend of these learning models depends on the online materials, the needs of the students, and the instructor requirements.

In our study, we define the blended learning as the coherent integration of face-to-face and e-learning to address our educational goals. When blended learning is understood and applied carefully, it will offer great advantage for students and teachers, Geraldine *et al.* (2012). Some of these advantages are as follows:

- Blended learning supports effective and strong socializing environment through face-to-face learning.
- Students' academic performance can be improved through blended learning.
- It allows reaping a profit by minimizing the cost of education, travel, and classroom.
- Blended learning can diagnose a student's learning level.
- It provides an environment for students to work in a relaxed environment, instead of moving through school.
- It gives students full control of their education.

In our approach, face-to-face and e-learning models are combined. Main courses such as programming and hardware-based courses are taught face-to-face and the other courses are taught online. Online courses part into two sections as synchronized and asynchronized. Asynchronous courses are applied through Learning Management System (LMS). Students can access the past courses; submit their homework and projects through this system. Additionally, they are allowed to choose how they will access the necessary learning materials. In synchronized section of the online courses, students join the class in specific time determined by the department. Through this education model, the courses are followed interactively and independent of location in the same time zone. Owing to developing technology, students now have the opportunity to participate in education remotely and communicate online without meeting face-to-face as it is in traditional learning model. It is important that the related e-learning process has been supported with also an intelligent program, which is based on teaching C programming language. In this way, it has been aimed to improve educational processes within the related course and the education approach in the department. The blended learning approach has been evaluated by the authors and obtained results show that the introduced artificial intelligence supported blended learning education program enables both teachers and students to experience better educational processes.

The rest of the paper is organized as follows: In Section 2, we define the blended learning and its components, explain internet based, computer based and mobile learning that comprise the online learning section of blended learning. Section 3 presents the application of blended learning on

Table 1. Differences between traditional learning and blended learning model

Main Features of Education	Traditional Learning	Blended Learning
Location	In Physical Classes (Not Flexible)	Anywhere (Flexible)
Learning Method	Face-to-Face	Face-to-Face and Online
Learning Time	At Specific Time (Not Flexible)	Any time (Flexible)
Technology Usage	No obligation for using the technology	It is a necessity to use the technology

Algorithm and Programming course that is taken by junior students in fall semester in Computer Engineering Department. In Section 4, we discuss about the Artificial Intelligence based program, which has been used along the e-learning side of the blended learning. Next, in Section 5, we discuss about the evaluation results of the performed educational application and finally, in Section 6, we provide conclusions of our study.

BLENDED LEARNING AND ITS COMPONENTS

In traditional learning, the classes are always physically located in specific places and the courses are thought at specific times. On the other hand, in blended learning, the learning process can take place at anytime, anywhere by benefiting from technology. Table 1 shows the main differences between the traditional learning model and the blended learning model Asif *et al*. (2012).

Blended learning is an educational model that is the combination of traditional (face-to-face) and online learning (e-learning) models Asif *et al.* (2012). It provides easily accessible and motivating learning environment by combining the motivation and inspiration of traditional learning approach with the convenience and flexibility of e-learning, Demirer et al. (2009). Online portion of blending learning model has two sub-parts that are network based and non-network based learning. While network based learning comprises of Internet and web based learning, the other part comprises of computer based and mobile learning. Figure 1 shows the components of Blending learning model Hadjerrouit *et al*. (2008).

Online Learning (E-Learning)

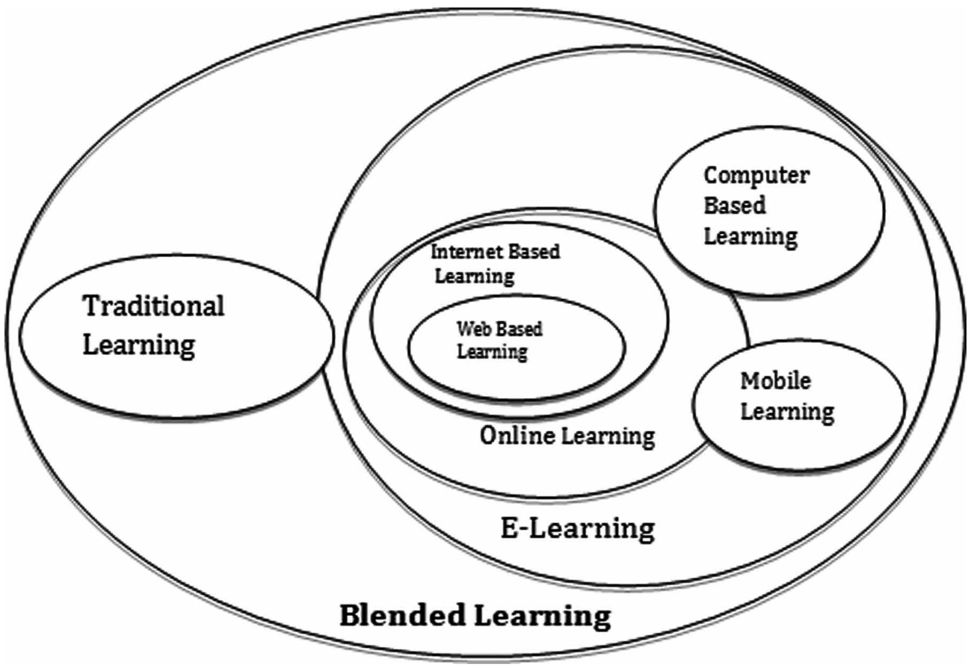
Rapid evolution of technology has a positive effect on education system and changes the education environment. With the widespread use of the personal computers and Internet, computer based learning has been popular and the education environment has moved to Internet. In 21st Century, this technology has been indispensable part of our lives and the name is changed to e-Learning.

e-Learning is a learning and teaching model that is designed to be carried out by using electronic media, Bourne et al. (1996). It is less expensive than the traditional learning approach, not limited to a specific geographic location and more flexible in terms of time. It replaces the traditional learning where it cannot operate. While the computers make the learning easier, Internet technology acts as a communication bridge interconnecting other computers and people making the learning process interactive, Bell et al. (2013). Online learning or e-learning has two sub-parts that are Internet and web based learning Hadjerrouit *et al*. (2008).

Internet Based Learning

The formal use of Internet Based Learning began with the establishment of moderated newsgroups in 1960s, Georgiev et al. (2004). However, it is a new type of distance learning model that uses the Internet technology to deliver the course materials to students Torkul et al. (2005). In this model, a virtual communication way is established between the students and teacher. On one end, teacher lectures and on the other end students join the class and take courses from different cities, countries.

Figure 1. Blended learning and its components



The learner does not only takes information, she or he also contributes, interacts, constructs the knowledge that enable the learning process, Hill et al. (2004).

Universities, colleges, schools, training facilities have seen the power of the Internet and this power removed the time and place barriers for the delivery of education:

- Many companies have begun to develop computer-based training software and continuing to develop software modules that are accessible via an Internet browser.
- HTML editors, web-publishing tools are being used by many educators to prepare assignments, presentations, post announcements, videos, animations. to support course activities.
- Corporate organizations are now focused on rich multimedia systems to share knowledge within the company and train their employees by teaching them the new technology.
- Virtual universities are being established that offer online courses and degrees using Internet technologies.
- Software development companies such as Google, Microsoft, Adobe have been developing sophisticated learning platforms that include interactive collaboration tools such as email, interactive discussion, shared spaces, video conferencing.

Although there have been many advancements in technology that empowers the Internet based learning, current bandwidth and speed limitations are the only limiting factors that prevents the Internet based learning from being the de facto technology standard for education.

Web Based Learning

We use the web to acquire information. In computer engineering education, the web is increasingly used as a learning tool and as a delivery method for online learning. Web based learning is similar to computer based learning that provides an environment independent of time and location, yet differs because web browser is used for communication, Khalifa *et al.* (2002). It is a hypermedia based teaching program that uses the resources on World Wide Web (WWW) to promote and support learning process in a rich learning environment. In this model, web is used as learning and teaching tool and it is not the main goal, Boisvert et al. (2000).

Current research on web-based learning shows that one of the effective ways of learning and teaching is using the technology. Teachers, trainers can create interactive course materials that include online activities, animations, and presentations via programming or plug-ins. These affect the learning process in a positive way, and learning is meaningful and enjoyable.

In these types of systems, students login with a user name and password assigned to them. It is possible to generate student reports containing the exact time a student connected to the system, duration of connection, information regarding the lectures he/she studied, quizzes, exams he/she took. In addition, students' course performance can be evaluated, students and the teacher can meet online and realize interactive learning activities.

There are several types of teaching strategies for Web Based Learning. By applying some of these strategies, computer-engineering education can be more effective. Some of these strategies are:

- **Discussions:** This involves establishing relations, discussing ideas with other students in the classroom environment. Teachers can assign reading tasks, start a discussion; students can gain access to e-mail, discussion boards, or chat with other students and teacher.
- **Interactive Support:** Teachers can evaluate students based on their work and provide feedback. Students have the opportunity to partner with other students and create a synergy. The support can be in any direction such as faculty-to-faculty, student-to-student, faculty to student and it can make use of whiteboards, discussion boards, cloud based sharing.
- **Data Sharing:** This involves data sharing with others locally or remotely sharing. The collected data can be further analyzed to conduct a research, produce results.
- **Collaborative Software Development:** Students have the opportunity to work on a project with others independent of location and time, code together to develop a software product, share resources such as databases, exchanging ideas and documents and work on the same document simultaneously. Teachers can comment on the work, identify the weaknesses and improve students' ability to code.
- **Simulations:** Online simulations can help students better understand how stuff works by seeing them in action.
- **Data Exploration:** Students can see real world cases, use Web data to make decisions, develop and test software based on the data that has been gathered from the web.
- **Online Practice:** This involves accessing and preparing online materials; practicing and applying acquired knowledge, create exercises; code software using popular programming languages such as Java, Flash and distribute them online.

Computer Based Learning

This type of learning model contains computer-aided education. Learning materials and activities are delivered via computers without connecting to a network, Inga *et al.* (2013). Computers are used as an environment where the learning takes place. They are not the purpose, yet a learning tool that provides information to learners Pea *et al.* (1990). The underlying principles of this learning model are stimulation, response and strengthen elements.

Along the learning process, students strengthen themselves by answering the questions directed at them and interact with the courses loaded to their computers that establish the learning.

There are many advantages of computer based learning in comparison to traditional face-to-face learning. Some of the advantages are:

- Location independency.
- Time and cost reduction.
- Ability to choose learning materials freely according to knowledge level and learning skills.
- Self-paced learning.
- Flexibility.
- Interactive learning.
- Applicability of different learning styles and facilitates the learning process.
- Develops computer and Internet skills.
- Building self-confidence, self-knowledge and encouragement through computer-based courses.

Although there are many advantages, there are some disadvantages. Some of these are:

- Causes falling behind if the students have low motivation or wrong studying habits.
- If students have weak computer skills, they may be confused or loose focus about course activities.
- Physical isolation from other students and the teacher.
- Unavailability of instructor when help is needed.
- Slow Internet connections or computers may have bad influence on learning.

Mobil Learning (M-Learning)

Mobile Learning (M-Learning) is the newest type of learning model where the learning process takes place in mobile phones or tablets, Georgiev et al. (2004). The term "Mobile" is also percepted as portability. Owing to this perception, the number of various devices and approaches that are to be used in this model has increased. M-Learning provides a new environment for the learning model that does not follow a formal and specific plan, Peters *et al.* (2010).

There are differences that separate this model from other learning activities. Most distinctive difference is that the learners are always on the move. This makes the learning process independent from time and location. The learner can start and interfere the learning process anytime, anywhere. Furthermore, people are to communicate with the rest of the world without needing big personal computers and cables.

According to the statistical data that International Telecommunication Union (ITU) published in 2013, currently, there are 6.8 billion mobile phones in the world, ITU *et al.* (2013). The results of this data shows that it is possible to reach these many people via M-Learning and how powerful this model can be. In the near future, integrating the flash animations, Web 2.0 tools and virtual reality applications to all mobile systems will make these platforms more attractive. Considering the advances in mobile technologies, fast Internet connection that the 4G technology provides and increasing number of mobile users, it is feasible to say that M-Learning will become more attractive, effective and it will be applied extensively in near future, Keskin *et al.* (2010).

THE APPLICATION OF BLENDED LEARNING IN COMPUTER ENGINEERING

This study analyzes the Algorithm and Programming course in an artificial intelligence supported blended learning program in 2012 and 2013 fall semesters. Before discussing about the artificial intelligence side of the work - approach, it is also better to talk about the general application of the blended learning approach in our study.

Table 2. Weekly schedule of algorithm and programming course

Schedule	Units	Course Subject
Week 1	Unit 1	Description of Algorithm, Using flowchart, Mathematical expressions Using conditional expressions in algorithms Loop algorithm
Week 2		
Week 3		
Week 4		
Week 5	Unit 2	Basic input/output libraries Basic input/output transactions
Week 6		
Week 7	Unit 3	While loop, Do-While loop
Week 8	Midterm Exam	Midterm exam that includes first three units
Week 9	Unit 4	For loop, infinite and dead loops
Week 10	Unit 5	Arrays, Powers of array: loops, character arrays and multi-dimensional arrays.
Week 11	Unit 6	Structures in C Pointer with Structures Nested structures in C
Week 12	Unit 7	Definition of pointers Usage of pointers Pointers with functions
Week 13	Unit 8	Description of Function Function prototypes Local and global variables Some most frequently used functions in C
Week 14	Repetition Units	Course Summary
Week 15	Final Exam	Final exam that includes all units

Algorithm and Programming course is given to the students who are enrolled in computer engineering program in Engineering Faculty in the first year of their education semester. The main purpose of this course is to help students gain programming abilities through participating in C programming applications. This course is taught for duration of 15 weeks with 3 hours theory, 1-hour lab. Subjects are divided into 8 main units as shown in Table 2.

Conceptualizing Phase: Programming Concept

Algorithm and Programming course is designed to support conceptualizing phase in blended learning model. The aim in this phase is to establish a connection between students past knowledge and course structure. The most important mission of the teacher is to eliminate the students' prejudgments about programming. Thus, the teacher needs to demonstrate that the students' past knowledge will help them to understand the new subjects about programming. For example, if the teacher is teaching while-loop structure and student has past knowledge of if condition, integers, students must be able to learn the new subjects by using their past knowledge. Teacher should prove that students' past knowledge is not the exact solution. If a student wants to create a set that includes ten numbers, they should use an array instead of defining ten variables. Therefore, the new learning concept is combined with students' past knowledge. According to Hadjerrouit et al. (2008), some pedagogical methods can be applied to algorithm and programming concept:

- **Multiple Presentations:** Multiple presentations should be used when teaching programming. The presentation can be linguistic, verbal, symbolic and pictorial. All programming concepts must include many kinds of presentations.
- **Comparison and Opposition:** Programming concept should include comparison and opposition.
- **Forward and Backward Samples:** Samples should be referenced according to previous programming knowledge and the new programming concepts.
- **Investigation:** Applicability conditions of programming concepts should be investigated.
- **Classification and Categorization:** Concepts should be classified and categorized according to the specifications of concepts.

Structural Phase: Programming Action

Algorithm and Programming course is redesigned to support structural phase in blended learning model. This model is a process that computer programs are created with task-based activities [In our study, we have supported these activities with also artificial intelligence based C programming program, which enables students to solve problems via intelligent feedbacks (the program will be introduced in the Section 4)]. During the process, students are directed to produce C programs. This process should be continuous and always renew itself. Students must be able to build application with the knowledge they have already learned. Difficulty level of application should be made incremental such as spiral model. Assigning tasks that are feasible in real life motivates the students during structural phase. According to Hadjerrouit *et al*. (2008), programming requires analytical and critical thinking abilities, which are as follows:

- **Analysis and Design:** Having the ability to analyze and design is crucial since the students always tend to code without analyzing and designing. Students should learn to analyze programming problems by gaining the ability to analyze and design. In analysis phase, they should solve the programming problem and design a suitable algorithm before coding. It is required for a student to develop these skills before coding.
- **Improvement:** This strategy is highly important. Some problems are resolved through prior encountered and solved problems. Students should be able to renew their knowledge and improve themselves to solve similar problems.
- **Comparison and Opposition:** Comparison and opposition are alternative methods for finding the most effective solution.
- **Estimation of Program Behavior:** Estimation of Program behavior is an important subject. Thus, students should be able to estimate the situations about program behavior.
- **Producing Alternative Solutions:** Students usually have only one way to reach the solution during coding. When they find a solution, they directly start coding, and never stop. However, this approach is not effective since they may be alternative solutions that are more effective.

Face-to-Face Conversation Phase: Interactions, Collaborations, and Discussions

Algorithms and Programming course is designed to support the face-to-face conversation techniques of blended learning model. In other words, it is evaluating the programming techniques and activities of students through dialogs. This approach can be applied parallel to the first and second education models or separately. According to Hadjerrouit *et al*. (2008), some pedagogical strategies may be applied to this approach:

- **Illustration (Summarizing, Defining, Discussing):** This strategy facilitates student learning by allowing them to explain the programming process, produce solutions for new conditions and applying ideas.
- **Meta-Communication:** Students generally think that a solution is only valid for a specific program. However, the program must be readable and understandable by others, thus facilitating fixing the program specific errors. Establishing a clear meta-communication is important for successful programming. Teachers should explain and emphasize the importance of meta-communication to the students.

Online Resources

Most important criteria for online resources that are designed for conceptualization are preparing accurate presentations, accessibility, and effective illustrations. These criteria have direct influences upon students. Strategies for online resource strategies that are designed for conceptualization are as follows:

- Explaining the programming techniques according to pedagogical principles.
- Designing user-friendly interfaces and providing accurate links for study materials.
- Explaining the programming concepts in a clear and understandable manner.

In the next phase, online resources are re-designed to support structural methods. Most important online resources for structural methods are as follows:

- Preparing well-designed online programming examples for students to work with.
- Providing interactive online support for students to solve programming problems.
- Providing program codes that are easy to use and modify.
- Preparing online presentations that contain multiple components such as text, graphics, pictures and symbols.
- Providing links to past online exams and programming exercises.

Finally, this course is re-designed to support face-to-face conversation phase of blended education model, discussing students' solutions for programming exercise, sharing solutions with students and teachers via e-mail and Internet.

Thus, online resources should contain the followings:

- Synchronized communication for students to communicate in real time.
- Asynchronous communication for accessing forums, e-mails at anytime, anywhere.
- Programming questions that are to be solved by students individually or with a group and graded, commented on by teachers.

In addition to the related online resources, the intelligent side of our blended learning model approach can also be evaluated in the context of online resources (actually, the artificial intelligence program could be analyzed in every phase - application side of our model). The program is some kind of online material and can be used by students along the learning activities. It can be expressed here that the program is the most important educational component of our model; among other online resources.

Applied Artificial Intelligence Supported Blended Learning Model

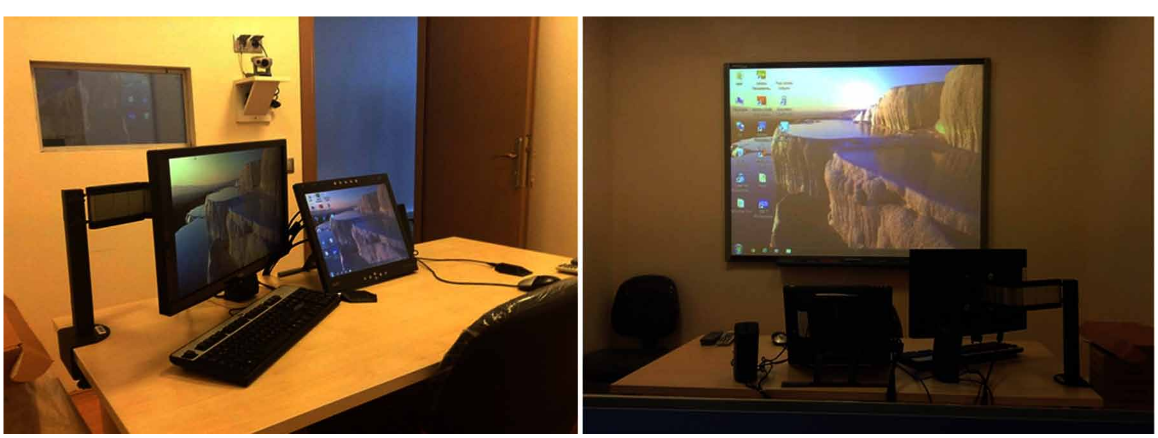
Application of our blended learning model involves three methods in learning cycle. First, the teacher determines the concepts and the programming activities to be taught every week through 15 weeks. The teacher identifies the insufficiencies of the applied methods by examining the activities and establishes links between previously known concepts with the new concepts to be taught. Along these activities, an artificial intelligence based C programming teaching program takes active role in order to improve the process.

The main purpose of the course is to teach programming and provide algorithmic reasoning skills to students. Teacher cultivates the students' abilities to understand the programming concepts. Subsequently, students endeavor to produce solutions for programming problems. For instance, if the programming concepts that are to be taught are related to "while loop", students perform activities related to "while loop" structure. Students work individually or by joining to small groups. The task of the teacher is to direct the students to think more deeply, creatively. Learning how to program is an iterative and continuous process that lasts for 15 weeks and comprises of renewal, improvement and change. Students spend their most important time on programming activities. Through this time, students provide solutions and present their ideas. Along these activities, they are also directed with the artificial intelligence based program as a supportive component. Briefly, it can be said that students are free to spend their time on the program; but in our study the teacher is more encouraged to decide when the program will be used by the students along the educational process. So, it has given a flexible, intelligent blended learning flow along the work. As another flexible aspect of the model, teachers also have had the opportunity to improve themselves, renew course materials, and change the way they teach by meeting students face to face or creating online surveys, polls.

Blended Learning Studio Environment

Computer engineering department has a studio that includes synchronous and asynchronous education that is a part of blended learning. The studio is built in a 15 m^2 area that has a high level sound insulation. The studio has a fully equipped computer, a high definition camera and a microphone to create an interactive course environment. In addition, there is a smart board, which provides a large screen for teaching, and a projector that reflects computer screen to smart board (Figure 2).

Figure 2. Some photos from the studio environment



Blended Learning Course Delivery Method

In computer engineering blended learning program, 30% of courses is taught face-to-face, and 70% is taught online. To protect the education quality, same teachers teach the courses in traditional education program and the distance education program. Additionally, students in traditional education program and blended learning program take the same exams at the same place. Teachers decide carefully when choosing face-to-face courses. Face-to-face courses must be suitable for online delivery and must enable interaction.

ARTIFICIAL INTELLIGENCE PROGRAM FOR TEACHING C PROGRAMMING

As it was mentioned before, the related e-learning process of the blended learning model of this study has been supported with also an artificial intelligence based program, which aims supporting the activities of teaching C programming language. The program has been designed and developed by Kose, and Deperlioglu (2012) along with some other Artificial Intelligence based programs, which were introduced in the context of their research work. Because the related programs have been applied successfully along different courses and caused positive results, programs have also been employed for some other experimental research works performed in different time and environment conditions (Tufekci, & Kose, 2013). From their work, the main features and functions of the program can be expressed briefly as follows (2012):

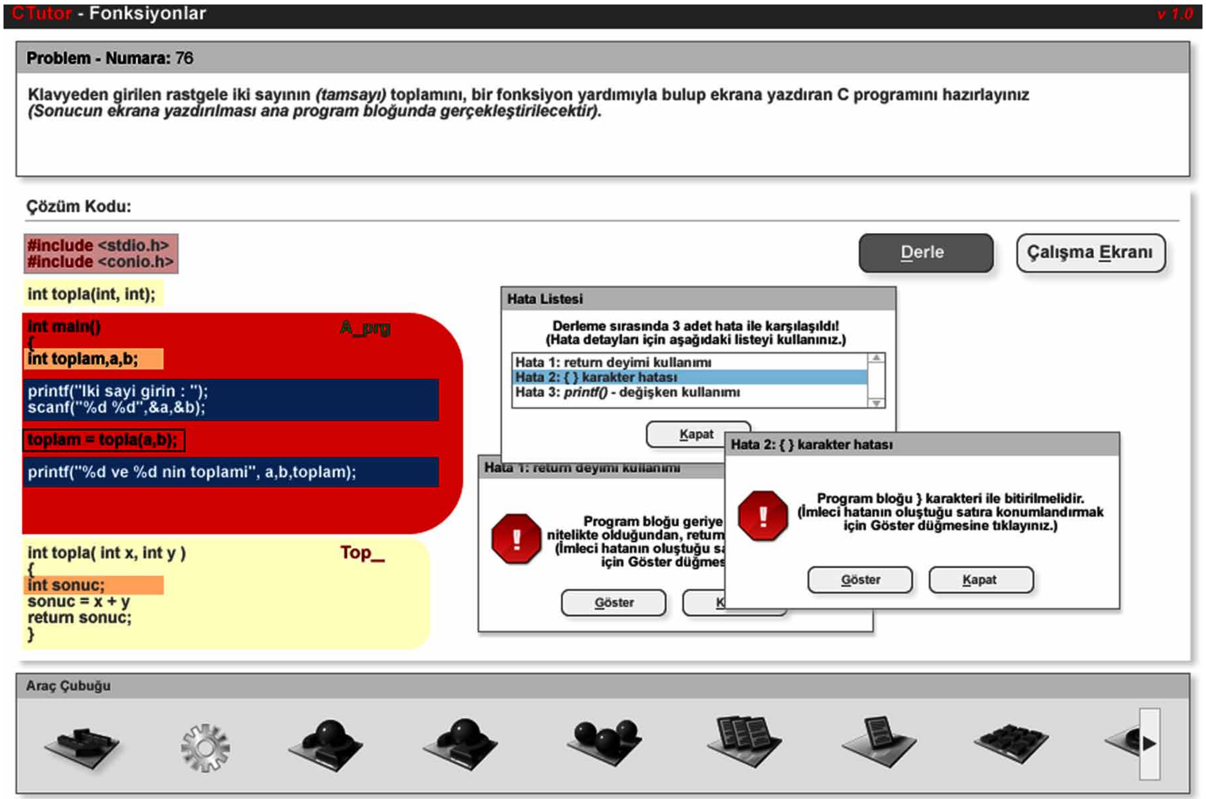
"The artificial intelligence based program for teaching C programming language is some kind of an intelligent learning environment in which students can take some exercises by using an easy to use interface and teachers can define new C programming exercises with the provided tools. The program allows teachers to create new exercises by using a management interface provided in the system. For each exercise, the teacher can define the problem text and develop what would be the correct solution to that problem in the same way as a student would do. Moreover, domain expert knowledge of the program can also be adjusted for specific exercises by using the management interface of the system. All of these operations can be done easily by using the interface supported with drag and drop feature and simple system controls.

From students' perspective, the program interface is some kind of tool, which assembles different system controls to get the representation of solutions and deliver exercises, feedbacks and information. Over this program, students must apply their knowledge on C programming to develop solutions for given exercises. Related solutions must be given in a special form, which can be parsed and understood easily by the system of the program. To achieve this, some specific using features and functions were included in the system. For instance, the system interface allows solution C programs to be built by means of a drag and drop feature, which limits the actions that can be done in the program and focuses students' ideas on solving processes instead of writing C source codes. Eventually, this function permits the program to trace all actions performed by students and facilitates the adaptation, which can be provided by the system."

Figure 3 represent a screenshot from the interface viewed by students (Kose, & Deperlioglu, 2012).

"The interface, which can be viewed by students, consists of three different parts. These parts provide all necessary elements, which enable students to understand problem of the given exercise, develop a possible solution for this exercise and view obtained results. The first part is located on top of the interface and used to show 'problem text' of the given exercise. Under this part, the 'workspace', where students can develop a solution C code for the given exercise, is located. By using this part, the student can start to create

Figure 3. A screenshot from the interface viewed by students



a solution C code or edit the developed one according to the received feedbacks. It is easy to edit any written code (block) by double-clicking on it. The workspace includes two buttons named as 'Compile' and 'Runtime Screen' respectively. The 'Compile' button is used to execute developed solution programs. On the other hand, the 'Runtime Screen' button is used to open a new window, where students can view the "runtime" of the solution program after the compiling process. After a successful compiling process, this window is also opened automatically by the program. The last part of the interface, which is also named as 'Tool Bar', is located under the workspace. The Tool Bar includes many different elements that can be used to develop a solution C program on the workspace. Students can use the provided elements to define different program parts like declarations, preprocessors, if statements, iteration (loops), functions…etc. Each element can be added to the workspace by dragging the element icon and dropping it into the workspace. When adding an element to the workspace, some additional information such as names, parameters, types…etc. is also requested by the system. The program also views different code types in separate 'layer' elements. This feature allows teachers and students to understand code structure easily and enables system to evaluate developed programs faster.

After developing a solution for the given exercise, the student can start the evaluation process by clicking on the Compile button. After the evaluation process, the program gives feedbacks about errors that were made within the solution program. Evaluation mechanism of the program is based on a domain prepared according to the expert knowledge. At this point, the domain of C programming is very complex. There is no fixed sequence of actions that will enable users to get the solution, nor is there only one solution for a given exercise. Indeed, there are an infinite number of C code combinations which will lead the user to a valid solution.

The program over here employs a student modeling called 'Constraint Based Modeling' for providing wide space of solutions. Constraint Based Modeling is based on Ohlsson's theory of learning from errors (Ohlsson, 1994). A formal notation has been introduced by Ohlsson and Rees to be used for constraints within models (Ohlsson, & Rees, 1991). The unit of knowledge is called as a state constraint and each state constraint is used as an ordered pair of $<C_r, C_s>$, where C_r is the relevance condition and C_s is the satisfaction condition. C_r identifies the class of problem states for which the constraint is relevant whereas C_s identifies the class of (relevant) states in which the constraint is satisfied. Each member of the pair can be thought of as a set of features or properties of a problem state. At the same time, constraints are encoded by rules of the form: *If C_r is satisfied, then C_s should also be satisfied; otherwise a principle is being violated*. Briefly, the domain model consists of a set of rules, which represent general principles that must not be broken (Corbett *et al.*, 1995)".

In the domain model of the program, some examples can be the followings (Deperlioglu, & Kose, 2012):

- C_r = 'a problem requirement is to apply a function to a range of numbers' and C_s = 'it must be the case that the solution program contains a loop'
- C_r = 'exist an assignation element' and C_s = 'it must be the case that there is a valid expression on the right-hand side of the element'
- C_r = 'exist an assignation element' and C_s = 'data types associated on both sides of the assignation must be equal'

In our study, we have also added some more examples - rules to the related domain model; according to our experiences along past educational processes at the Suleyman Demirel University Computer Engineering Department. In this way, we have also aimed to improve the standard model of the program employed here.

EVALUATION

The artificial intelligence supported blended learning approach has been applied along one term, in order to figure out if usage of such "intelligent educational approach" can enable students to experience effective educational processes and improve their academic success levels. As it was also mentioned before, the application has been based the Algorithm and Programming course; during 2012 and 2013 fall semesters. More details regarding to the course content and educational objectives have been expressed briefly under the Section 3.

In the context of the evaluation processes, experimental evaluation and student survey based evaluation methods have been performed. More details regarding to these methods and obtained results are presented briefly as follows:

Experimental Evaluation

In the experimental evaluation, a total of 200 students (from Computer Engineering Department of the Suleyman Demirel University, Turkey) have taken active part. 100 of the related students have formed the experimental group which will experience the artificial intelligence supported blended learning approach. Then remaining 100 students have formed the control group which will experience the traditional - default lectures. It is important that the groups were formed as balanced, according to the chosen students' academic success levels. The related experimental evaluation has been based on the percentage of students who have

Table 3. Obtained experimental evaluation results at the end of the term; for the algorithm and programming course

Group	Number of Students	Number of Students Who has Passed the Course	Mean Success Grade
Control	100	63 (63%)	64,88
Experimental	100	82 (82%)	76,30

passed the Algorithm and Programming course, and also on mean grades of the groups. Passing the related course needs having a success grade, which is equal to or bigger than 60 [The success grade has been calculated via (0,4 * visa exam grade) + (0,6 * final exam grade)].

Table 3 presents the obtained experimental evaluation results at the end of the term; for the Algorithm and Programming course.

As seen from the results, it can be said that using Artificial Intelligence supported blended learning approach has enabled students to improve their grades and success levels for the Algorithm and Programming course.

Student Survey

In addition to the experimental evaluation method, a student survey based work has also been performed at the end the term – course. At this point; students, who have taken part in the experimental group, have filled a survey to give feedback about their opinions on 10 different statements regarding to the performed educational process and also employed intelligent C programming teaching program. Students have expressed their opinions on the Likert scale.

Statements provided in the performed student survey and the received responses for these statements are presented in Table 4.

According to the feedback - responses received via the Student Survey, we can express that the students had enjoyed the performed artificial intelligence supported blended learning process, liked using the intelligent C programming teaching program and had positive experiences along the application. It is also remarkable that they think their academic success levels have been improved and they also think positive on applying the related educational approach - process in other technical courses.

Table 4. Student survey statements and the received responses

S. No	Statement	Responses for:*				
		1	2	3	4	5
1	"Thanks to the intelligent C programming program, I felt more self-confident about learning course subjects."	0	2	3	9	86
2	"I think it is better to take part in such intelligent blended learning processes rather than other approaches."	1	1	4	16	78
3	"I don't want to take part again in such learning - education process."	87	5	7	1	0
4	"I enjoyed the educational process performed along the term."	0	0	7	8	85
5	"By using the intelligent C programming teaching program, it is more effective to learn C."	0	4	8	14	74
6	"I felt that it was easier to learn difficult algorithm and programming subjects, thanks to the intelligent C programming program."	0	2	5	11	82
7	"It was difficult to use the intelligent C programming program."	79	11	9	1	0
8	"My academic success level has been improved after this learning - education process."	0	0	0	23	77
9	"I felt bored while studying on the intelligent C programming program."	80	11	8	1	0
10	"I think this learning - education process should be applied also in other technical courses."	0	4	6	8	82

* Likert Scale:
1: "I strongly disagree" 2: "I disagree" 3: "I have no opinion" 4: "I agree" 5: "I strongly agree"

CONCLUSION

This study introduced the application of an artificial intelligence supported blended learning approach in Computer Engineering education. It is remarkable that the blended learning is one of the most appropriate educational solutions that can be applied in order to combine advantages of different educational aspects. Because of this, application side of our study has benefited from advantages provided by the blended learning. In this sense; in addition to the advantages of the blended learning, we have also employed an intelligent C programming teaching program in order to improve effectiveness of the educational process. Briefly, the employed program is based on using intelligent feedback mechanisms for directing students to solve C programing programs by thinking about their mistakes in the code structures. As an intelligent learning environment, the program is effective at enabling students to perform their own-learning process in an efficient way.

The introduced educational approach has been employed at the Algorithm and Programming course of Computer Engineering program given at the Suleyman Demirel University. For the application, resources of the university have been activated greatly along the term: 2012 and 2013 fall semesters. In the context of the evaluation, results of the performed experimental and student survey related evaluation processes show that the introduced "intelligent learning solution" is effective at enabling students to gain necessary theoretical and applied knowledge, and abilities on C programming. In terms of the applied learning model, students were satisfied with the educational activities, which caused positive experiences during the process. More generally, obtained results encourage the authors to apply the related approach in different kinds of technical courses given at the Computer Engineering Department.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Study and development of intelligent machines and software that to perform the tasks requiring human intelligence.

Asynchronous: Not coordinated, not occurring at the same time.

Blended Learning: A learning model that is enriched with traditional learning method and online education materials.

Distance Education: Education in which students receive instruction over the Internet instead of going to school.

E-Learning: Internet based learning model that provides access to information independent of time and location.

Mobile: Being portable, the ability to move or to be moved.

Studio: Sound isolated workroom.

Synchronized: Being simultaneous, occurring at the same time.

Chapter 17
A Blended Course to Teach Graphical Programming Using LabVIEW

Yücel Uğurlu
Aoyama Gakuin University, Japan

ABSTRACT

In this chapter, the authors introduce a blended learning approach where LabVIEW, an e-learning environment, was integrated into a traditional graphical programming course for engineering students to teach advanced topics and to increase the programming skills of the students. In this course, the students were required to design projects using technology. The students designed small projects and frequently accessed the e-learning system to build real-world applications. The projects that students designed stimulated them to use the e-learning system. The impact of blended learning was evaluated on the basis of student surveys and certification test results. Experimental studies show that blended learning produced higher results in the students' self-assessment and certification test.

INTRODUCTION

Over the last decade, learning environments have changed considerably. Gone are the days when the only learning option was a face-to-face classroom experience, where the teacher came in and delivered a lesson or lecture on the topic of the day. Today, learning options include traditional, blended, and fully online education. To teach in these environments, educators have adopted a variety of pedagogical strategies and innovative technologies to enable better learning in higher education (Nistal, 2011; Macias, 2012; Maloy, 2010). The face-to-face strategies have been combined with technological tools and e-learning processes to form blended courses. Currently, 93% of higher institutions say they use blended learning strategies. Furthermore, they expect more than 40% of their courses to be blended by 2020 (Werf & Sabatier, 2009).

It is important to note that both components of blended education (traditional and online) have their benefits and challenges. In fact, no single learning environment is suitable for all learning needs. Educators who are interested in offering blended instruction need to be aware that they will

DOI: 10.4018/978-1-4666-8246-7.ch017

probably require various learning technologies in addition to traditional methods in providing an optimal learning experience that meets the needs of all students. A blended learning program combines e-learning and traditional learning methods (Bonk & Graham, 2005). Like many advances in educational practice, blended learning is defined and implemented in multiple ways. Statistics show that a number of schools and instructors have adopted blended learning, and the number has been increasing (Allen & Seaman, 2008). As more schools have adopted blended instruction, several different forms and practical usages have evolved. Many educators believe that blended learning is the best solution to today's educational challenges (Mendez & Gonzalez, 2011; Hadjerrouit, 2008; Hoic-Bozic, 2009).

To gain clarity and a deeper understanding of blended learning, there is a strong need to share the best practices in blended education. Additionally, investigating the impact of blended teaching and learning is extremely important. In this way, we can decide the best way technology can be used in the classroom and understand how it will affect student learning (Golden, 2006; Mohammad, 2012; Zhanga, 2006). Several studies have found that e-learning is as effective as or better than the traditional university class structure (Cybinski & Selvanathan, 2005; Gao & Lehman, 2003; Ho & Kuo, 2010). On the other hand, the results can vary according to the content taught, delivery method of the digital content, e-learning integration techniques, and motivation of students (Hasegawa, 2013). Therefore, more studies are required in order to completely understand the overall impact of blended learning in any discipline, particularly in engineering education. Engineering education has to deal with multiple levels of intelligence requiring intensive and one-on-one interaction with the instructor. Engineering students must be able to work across many different disciplines and fields and make the connections that will lead to deeper insights, more creative solutions, and the capacity to get things done.

BACKGROUND

The goal of the blended approach is to combine the best elements of face-to-face and online instruction. Classroom time can be used to engage students in advanced interactive experiences, while the online portion of the course provides multimedia-rich content anytime and anywhere there is Internet access—such as in computer labs, coffee shops, or at home. The students thus have more flexibility in their study schedules (Garrison & Kanuka, 2004). Moreover, there is early evidence that blended instruction can result in learning outcome gains and higher enrollment retention (Lim & Morris, 2009).

Blended learning is gaining popularity in higher education, although there are no rules in place to prescribe what the ideal mix might be. The term "blended" encompasses a broad continuum and can include any form of integration of face-to-face and online instructional content. The combination of face-to-face and online materials varies depending on the course content, needs of the students, and preferences of the instructor.

The following case study explores an efficient approach for blended learning in teaching graphical programming in higher education in Japan. This method has been implemented for science and engineering students in the last three years, and its positive impact on their learning has been demonstrated by the results of student surveys and final exams.

METHOD

A Description of the Traditional Course

In this chapter, a graphical programming course is introduced, along with the details of how the course was implemented in the traditional teaching approach. Graphical programming is most frequently used in the stages of engineering systems design. Engineers and programmers use graphical programs to translate information about physical events, such as vibrations and temperatures, into visual readouts. LabVIEW is a graphical programming environment tightly integrated with measurement hardware for engineers and scientists to quickly produce solutions for the acquisition, analysis, and presentation of data.

Graphical programming is a useful environment in engineering education, and it is offered to students who do not have a strong background in text-based programming. Engineering students can create a program using function blocks, wires, and loops in place of text strings, which looks similar to their whiteboard drawings of an application, instead of translating high-level design to specific text strings. In this way, they can easily build a PC-based virtual instrumentation (VI) system, which is advantageous to engineers and scientists who require increased productivity, accuracy, and performance. With virtual instruments, engineers and scientists build measurement and automation systems that are customized to their needs (user-defined) instead of being limited by traditional fixed-function instruments (Virtual Instrumentation, n. d.).

LabVIEW provides an entire development environment that makes the process of application development faster and easier. LabVIEW is a productive development environment for creating custom applications that interact with real-world data or signals in fields such as science and engineering. LabVIEW itself is a software development environment that contains numerous components, several of which are required for any type of test, measurement, or control application (Ugurlu & Nagano, 2011; Berger, 2009; Johnson & Jennings, 2006; King, 2012).

A LabVIEW-based graphical programming course has been taught at the Aoyama Gakuin University for the last three years. It is positioned as a multidisciplinary engineering course, and students from various departments are allowed to enroll. The class is organized to provide both theoretical and hands-on experience in graphical programming. Every student uses his/her own PC in the classroom, and hands-on lectures are conducted each time. The students use the student edition of LabVIEW as the graphical programming environment and a USB-type portable data acquisition device (myDAQ) as a hardware platform (NI myDAQ, n. d.).

The LabVIEW-based graphical programming course covers the following topics:

- Virtual instrumentation.
- LabVIEW programming environment.
- Execution, debugging, and handling errors.
- Data types and structures.
- Arrays and clusters.
- Subroutines and VI projects.
- Charts and graphs.
- Strings and file inputs/outputs.
- Data acquisition using portable hardware devices.
- Applications of graphical programming.

Students acquire analog or digital signals from various sensors using an NI data acquisition device and LabVIEW in the PC environment, and apply additional algorithms to build PC-based automation systems, such as a speech recognition-based on/off system, autonomous robot navigation, and image processing for student tracking. The course runs for 15 weeks, with 30 hours of teaching time.

Initially, the programming class focused on the traditional teaching approach, using slides, demos, and student assignments. We explained the programming techniques of LabVIEW and built sample programs step by step in every class. Students replicated the programs using their own PCs and thus understood the practical usage. In addition, we allocated 30 minutes per week to student design projects, during which students in groups of four or five worked together on their design projects and asked the instructor questions about their problems or recent progress.

Integration of an E-learning System

The traditional portion of the course only covers the fundamental techniques of LabVIEW programming; it does not explain the advanced features and practical implementations extensively. Therefore, e-learning content was introduced to supplement the face-to-face learning. The system provides videos and text for each topic based on tutorials, and it is easy to navigate and search for personal interests or needs. The e-learning system was developed in a separate server using a professional learning management system (LMS). A different instructor, not the one who has been teaching the face-to-face course for the past three years, was asked to develop the e-learning sections.

Figures 1 and 2 show the screenshots of some of the e-learning sections that were developed by the instructor in collaboration with the Aqtair and National Instruments Japan Corporation. The portal that was used consists of more than 200 topics and 30 hours of learning time, all dedicated to teaching graphical programming in LabVIEW to engineering students. The e-learning content included various components such as 5–10 minute videos (Figure 1), readings, and quizzes (Figure 2), and covered a variety of topics. A typical e-learning environment is shown in Figure 1, which explains the programming techniques of LabVIEW step by step. The user is able to select the subtopics from the right-hand side, while the check symbol indicates the competed topics. The user can stop the video or slide at specific times and topics. In the left-hand side, the programming environment of LabVIEW is displayed with its front panel and block diagram. Similarly, Figure 2 shows a typical multiple choice quiz environment. The user can see the correct answers only when he/she has completed the quiz. He can go back or skip the questions using the arrows at the right-hand side of the screen.

The e-learning portal is organized in six chapters:

- LabVIEW programming I.
- LabVIEW programming II.
- Data acquisition and analysis.
- FPGA (field-programmable-gate-arrays) programming.
- Real-time programming.
- Image acquisition and processing.

LabVIEW programming I and II cover basic, intermediate, and advanced topics of the programming environment. Data acquisition, FPGA, real-time programming, and image processing introduce practical applications of LabVIEW that can be used in student design projects, in combination with various plug-in hardware devices. The e-learning system is available to all students from the beginning of the course up to the final exam.

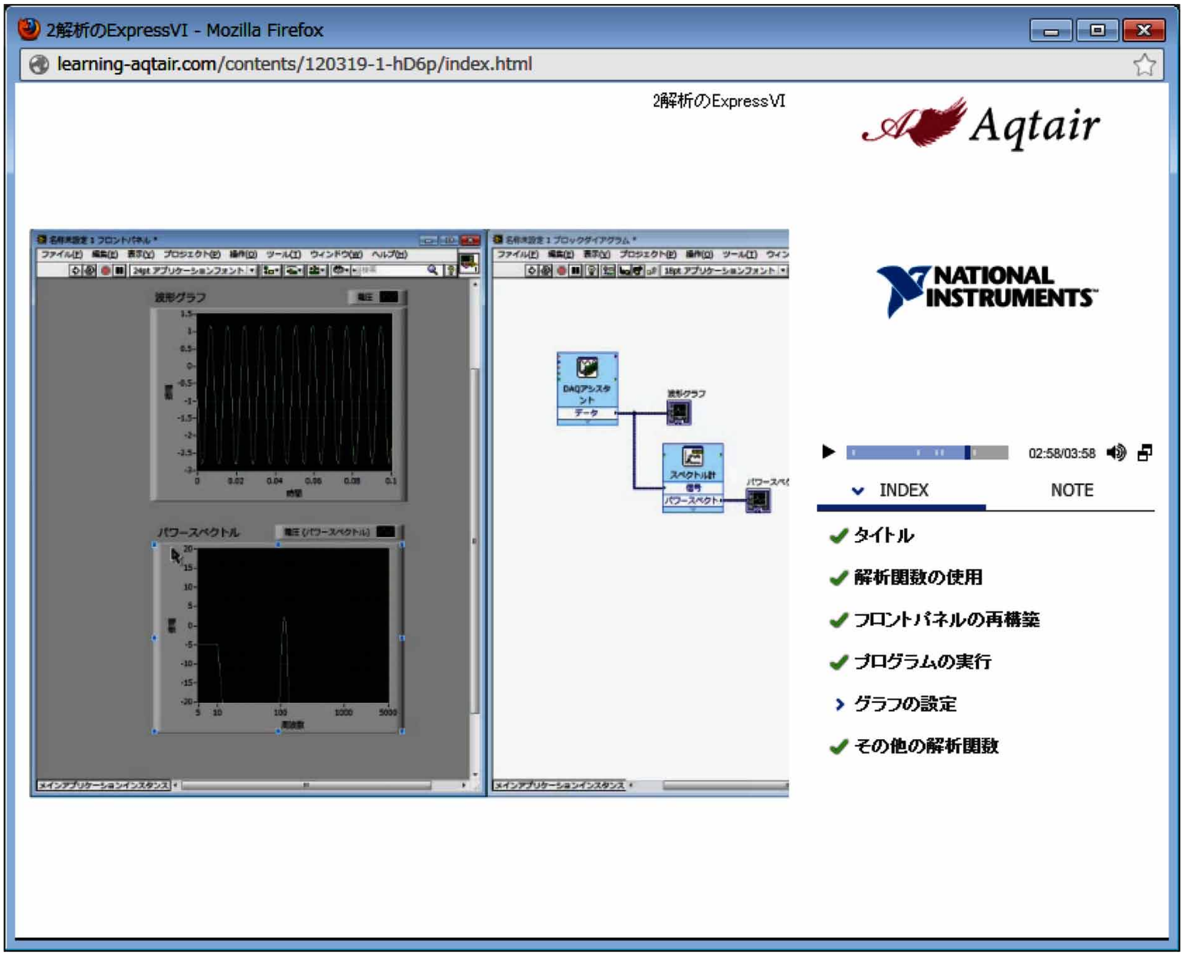
In the e-learning system, a student is given a unique user ID and password, which enable him/her to access all e-learning functions. Since students use their IDs to log into the system, it is easy to acquire their access history. The average view rate is 3.2 hours of e-learning usage, which is almost 10% of all digital content during three months of total access time.

Blended Course

A LabVIEW programming course has been taught at Aoyama Gakuin University for the last three years—two years in a blended format. The class is included in multidisciplinary engineering courses; 43 students from multiple departments enrolled last year. We have organized the class to provide both theoretical and hands-on experience in graphical system design. The overall course spans 15 weeks and includes 30 hours of teaching. After two weeks, the same course was blended with e-learning technology to enhance the programming skills of students.

Table 1 shows the number of students enrolled in traditional and blended courses (27 and 43, respectively). We conducted the course in a traditional way in the first year, and then ran the same course in

Figure 1. A video of the e-learning system



a blended format in the second. Therefore, student enrollment was rather higher in the second year. In both courses, students came from various departments and had no experience in LabVIEW. There were more electrical and mechanical engineering students in the blended course and more information science students in the traditional course.

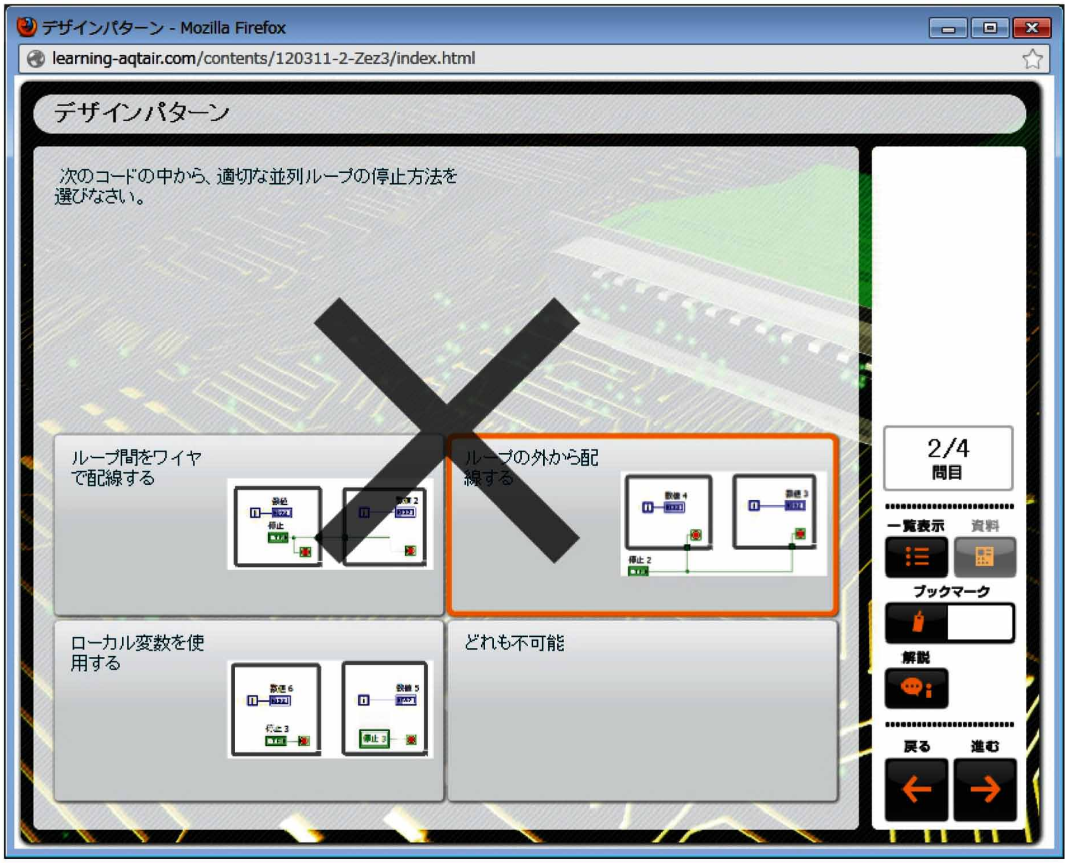
The students were granted free access to the e-learning portal to encourage them to use it, especially to be able to understand advanced topics and be successful in their design projects. However, e-learning usage was not mandatory, just an option for them to better understand and see the practical applications of graphical programming. Therefore, we explained the main benefit

Table 1.Student enrollment in traditional and blended courses

Disciplines	Traditional Course	Blended Course
Information	10	7
Electrical & Electronics	2	10
Mechanical	8	16
Management Technology	0	1
Fundamental Science	6	5
Bio-Science	1	4
Total number of students	27	43

Note. Traditional and blended courses have been implemented in consecutive years in the college of science and engineering at Aoyama Gakuin University.

Figure 2. A quiz on the e-learning system

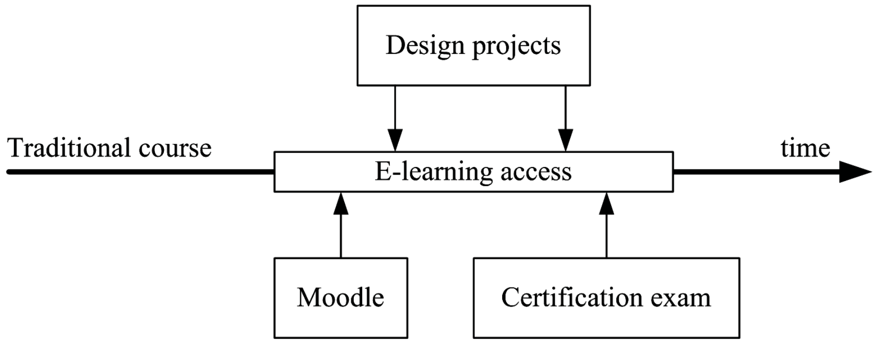


of e-learning during face-to-face teaching and showed typical examples to stimulate student usage. After that, the students asynchronously accessed the e-learning website based on their individual needs and interests.

The traditional course method and e-learning content were blended using the techniques described below. Figure 3 shows an overview of the blended teaching approach.

1. **Face-to-Face Introduction:** Traditional teaching approaches still have a better influence on students, especially in Japan. Therefore, we allocated a specific time in the classroom and showed the features of the e-learning system. We explained the main benefit and stimulated the students to proactively use the system.
2. **Moodle Announcements:** The Moodle course management system (CMS) was utilized to share the teaching materials, such as sample programs, power point slides, and weekly assignments of the design projects. Then, periodic updates and reminders were sent from the system to encourage students to access the e-learning portal. In particular, video and text-based on-demand e-learning modules were introduced so the students could conduct self-paced study and master the programming experience by learning advanced techniques and seeing real examples. When we scheduled the Moodle announcement, the student access rate increased.

Figure 3. Blending method using a traditional course and e-learning system



3. **Design Projects:** Project-based learning offers a wide range of benefits to both students and teachers (Mills & Treagust, 2003). Projects put students in active roles, such as inquirers, problem solvers, decision makers, and investigators. Therefore, we initiated several design projects for the students, who had been divided into groups, and gave them a chance to present their product in the classroom. Design projects were picked by students based on their personal interest, experience, and level of challenge. To complete the design projects, students accessed the e-learning sites to look at successful examples and learn new features of LabVIEW, such as low-level data and image acquisition and processing, etc. Design projects inspired students to investigate new features and revisit certain topics covered in face-to-face learning. In the design projects, 4−5 students were put in a group, and they worked together to build some real-world applications. Typical student design projects were the voice changer and recognition, light detection for an automated door opening system, earthquake detection for home safety, and remote vehicle control system. Figure 4 shows the examples of the student design projects for an earthquake detection system. The block diagram of the LabVIEW code is given in Figure 5.

Student Surveys

The survey results of the traditional and blended courses are compared to understand the overall impact of e-learning on students' programming skills. The survey, composed of six questions for evaluating the overall course, was announced right after the final exam using the course management system (CMS). The same set of questions was used in both the traditional and blended courses, and the students were asked to complete it within two weeks. An online survey tool called Survey Monkey was used; five levels of evaluation criteria were set up, where 1 corresponded to "poor" and 5, "excellent." A total of 53 students participated: 18 (out of 27) from the traditional course and 35 (out of 43) from the blended course. The results are summarized in Table 2.

Table 2. Student survey results

Survey Items	Traditional Course (Average)	Blended Course (Average)
Course coverage and content	3.6	3.8
Progress of the course	3.9	3.9
Demos and sample programs	4.0	4.1
Advanced applications	3.1	4.0
Idea and support for design projects	2.7	4.1
Overall course evaluation	3.46	3.98

Note. The evaluation criteria were 1: poor, 2: fair, 3: average, 4: good, 5: excellent.

Figure 4. An earthquake detection system using LabVIEW and myDAQ

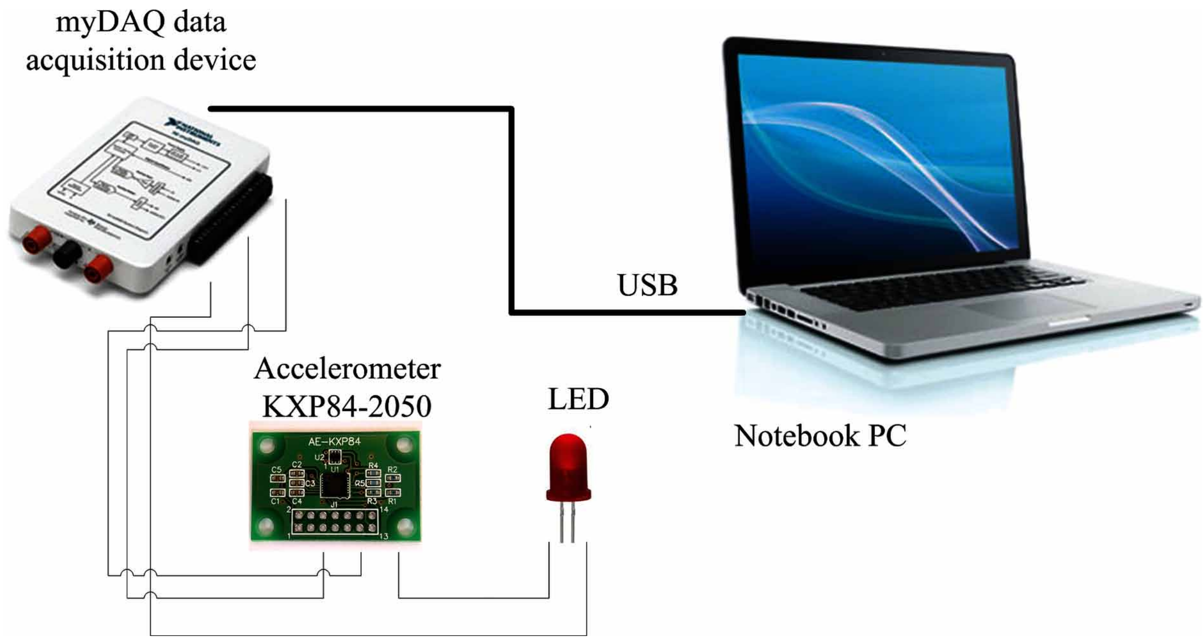


Figure 5. Block diagram of the LabVIEW code

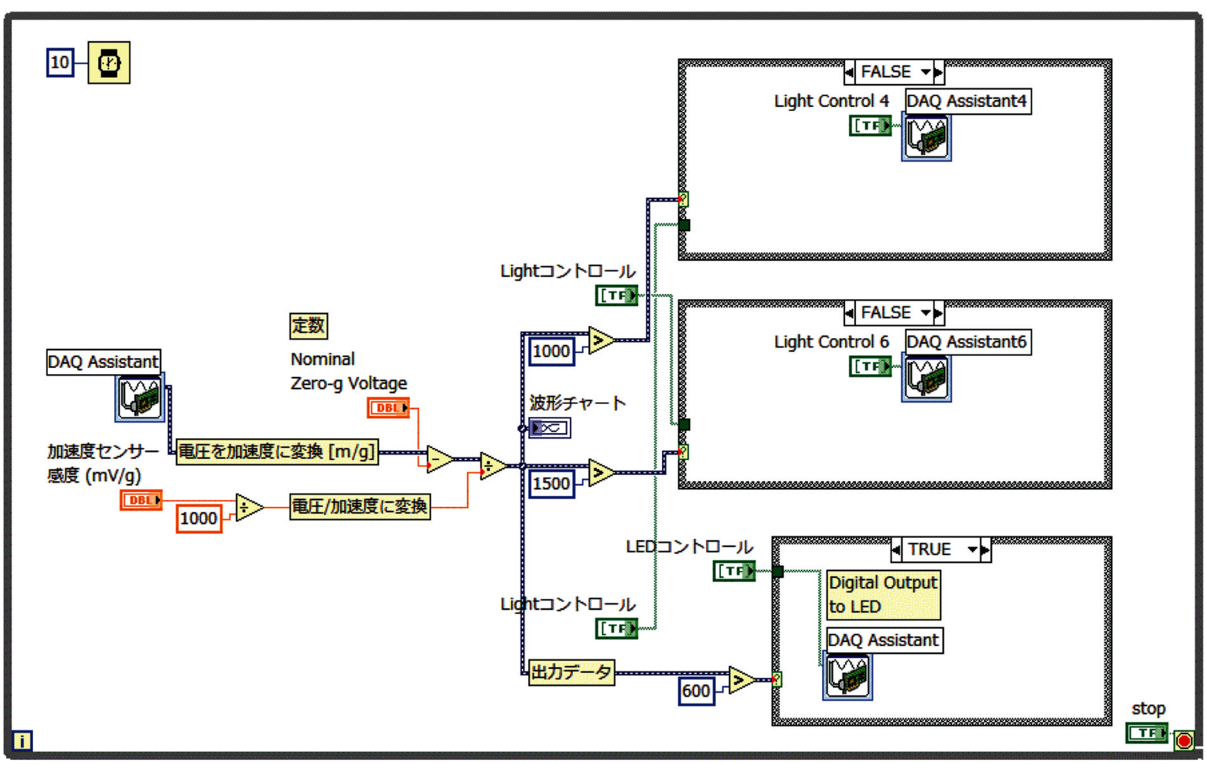

As shown in Table 2, course coverage, the progress of the course, and demos were not changed in both the traditional and blended courses. However, topics related to advanced applications and the design project were mainly covered in the e-learning format. Therefore, student evaluation results were higher in these specific items. Since students utilized the e-learning system based on their personal needs, their satisfaction level was higher than in the traditional approach, and the survey results were significantly improved. The overall course evaluation was calculated based on the average value of the five survey questions. The mean values for the traditional and blended courses were 3.46 and 3.98, respectively—a 15% improvement. The survey results showed that blended learning significantly enhanced the students' self-assessment on programming skills and was able to teach some advanced programming topics. On the other hand, the traditional course focused on fundamental topics, and student programming skills depended on the course coverage. Popular online topics included data acquisition, advanced programming features, and teaching materials related to the design project that were not covered in traditional courses.

Certification Test Results

Thus far, the impact of blended learning was evaluated from the students' perspective. However, to have a deeper understanding of blended learning, we also needed to evaluate the results from an objective perspective. Hence, a LabVIEW certification test was scheduled. The certification test indicated a broad working knowledge of the graphical programming environment of LabVIEW and the ability to read and interpret existing code. We adopted the LabVIEW certification test to assess and validate the programming skills of students as a final exam. In practice, the LabVIEW certification test is executed and evaluated worldwide by the National Instruments Corporation to achieve a global standard (NI Certification, n. d.). In this test, students are required to answer 40 multiple-choice questions on paper within one hour.

To measure the impact of blended learning, the average scores of the traditional and blended courses in the certification test were compared. The average class values were 43.17 and 48.14 out of 100 for the traditional and blended courses, respectively. The comparative results showed that the mean scores improved 12% when the students had 3.2 hours of e-learning modules. The simple difference in averages is not reliable enough to determine the degree of significance. Therefore, statistical analysis is applied using the t-test and p value. The t-test assesses whether the means of two groups are statistically different from each other. We obtained $t=2.1888$ and $p=0.0401$ in the certification scores of the traditional and blended courses. Since $p<0.05$, the difference is considered statistically significant.

In general, certification test results vary according to the sample population, motivation of students, programming experience, and learning methods. Our sample motivation was not exactly the same in the traditional and blended courses, but it included enough students from all departments. Similarly, the survey results show that student motivation was not very different in either course. All the students did not have previous experience in graphical programming, and the LabVIEW concept was new to them. Finally, traditional and blended learning methods were the main reasons for the difference effects the certification test results.

CONCLUSION

A blended learning environment was introduced and the e-learning system in teaching graphical programming courses in higher education was examined. Practical implementation showed that the blended approach was successful in teaching graphical programming using LabVIEW. The blended approach was well received by students because of its rich content and user-friendly environment, and because it covered important engineering applications.

The impact of the blended learning system was evaluated using the student survey and certification test. Survey results showed that e-learning was a useful tool when students went through specific e-learning topics. The main contribution of blended learning is the customization of learning content according to the students' personal interests. Therefore, they are motivated to learn advanced topics and practical applications to be successful in their design projects. In addition, the certification test was used to evaluate blended learning because the test is implemented using global standards. The results indicate that blended learning has a positive impact in students' programming skills.

FUTURE WORK

Our case study represents a group of students and targets a specific programming course in Japan. Thus, the general impact of blended learning might not be similar for different courses, students, and countries. Additionally, adapting the e-learning system to the regular courses will affect student motivation and real usage. Therefore, further investigation is required to produce more general and detailed results. In the future, the adaptation of blended learning to various teaching courses and student populations can be considered to motivate and inspire them, thereby enabling them to meet various engineering challenges.

KEY TERMS AND DEFINITIONS

Asynchronous Learning: A student-centered teaching method that uses online learning resources to facilitate information sharing outside the constraints of time and place among a network of people.

Blended Learning: Education that combines face-to-face classroom methods with computer-mediated activities.

Course Management System (CMS): A software package that provides Web-based infrastructure for the sharing of digitized information among teachers and students.

Graphical Programming Language: Also called visual programming language, in which the source code is itself graphical and does not principally consist of text.

LabVIEW: Stands for Laboratory Virtual Instrumentation Engineering Workbench, a system design platform and development environment for a visual programming language from National Instruments.

Learning Management System (LMS): LMS is a software application for the administration, tracking, reporting, and delivery of educational courses and training programs.

Project-Based Learning (PBL): An instructional method that provides students with complex tasks based on challenging questions or problems that involve problem solving, decision making, investigative skills, and reflection that includes teacher facilitation but not direction.

Synchronous Learning: A learning environment in which everyone takes part at the same time. A lecture is an example of synchronous learning in a face-to-face environment, where learners and teachers are all in the same place at the same time.

Virtual Instrumentation (VI): A customizable software and modular measurement hardware to create user-defined measurement systems.

Chapter 18
Fantasy Workshop:
Active Use of a Learning Management System (LMS) as an Approach to Blended Learning

Hilde Sundfaer
Åsveien Elementary School, Norway

ABSTRACT

Fantasy Workshop is a project focused on the active use of a Learning Management System (LMS), its-learning, in teaching and learning in a K-12 blended environment. As teachers in this study, the authors used an LMS as a learning platform in their 6th grade literature class. The focus for the class was creative writing and learning about Fantasy, a fiction genre. The aim of the project was to enable all students, not only those students who love to read and write, to learn about the Fantasy genre in a way that would build on their previous knowledge and interests. In addition, the project was aimed at facilitating students' writing processes in such a way that was meaningful and motivating for all students. Most importantly, as teachers, the authors used this project to establish an effective blended environment that worked for teaching and learning in the 6th grade classroom.

INTRODUCTION

The background for this chapter is a project we were involved in while we were at Nord Trøndelag University College in Norway in spring 2012. The main focus of this chapter is to share the teaching and learning experiences in our elementary creative writing classroom where we implemented blended instruction. We wanted to find out whether integrating a digital environment into our face-to-face class will help engage all students in the writing process as they learn about different literature genres. The results presented in this chapter demonstrate how the use of digital media can provide elementary students a greater sense of value in working with creative writing and learning about genre in K-12 schools.

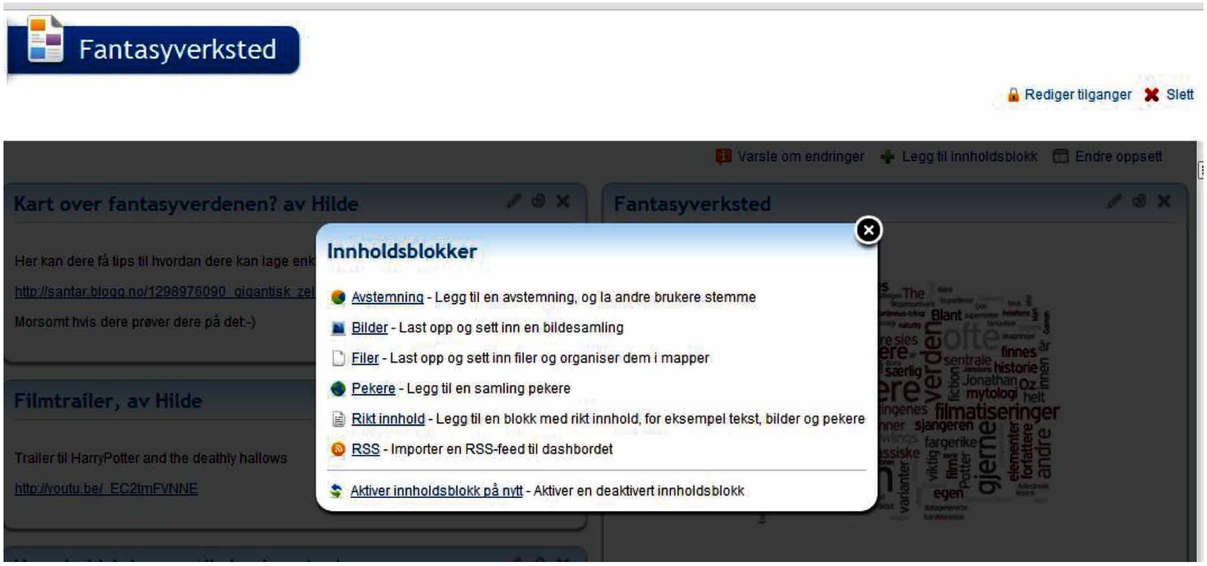
DOI: 10.4018/978-1-4666-8246-7.ch018

Figure 1.

For our digital environment, we adopted an LMS called “itslearning”. “itslearning” is a learning management system that is used in many schools, colleges and universities in Norway. It is also used in several teaching institutions worldwide. One of the functions of this LMS is that it allows one to construct theme pages, plan and publish creative work, and assess the creative works of others using different types of media. In our classroom, most of the students’ work was conducted in a tool known as “Page”. The interface of the Page tool is quite similar to the wall in the Facebook social media networking system (see Figures 1 & 2). The Page tool was mainly used to inspire our 6th grade students to connect with and provide feedback to their peers as they worked on their individual projects for the class. During the project our students were encouraged to seek advice from their peers regarding their texts and published music, movie clips and pictures related to the Fantasy genre. Some of the students even made their own short movies with book reviews that were published on the page. Hence forth, we will refer to the project as “Fantasy workshop”.

The learning objective for the Fantasy workshop was for our students to work on a project that will enable them gain a broader understanding of the Fantasy genre. In order to achieve this objective each student was asked to publish and share on the class’ Theme Page using text, internet resources, as well as the tools in the itslearning LMS. Students were encouraged to include sound, pictures, and weblinks in their project. The idea was to get the students to use the Page tool to inspire and support

Figure 2.



each other through the process of writing their own story. An underlying goal for us as teachers was to find out if this process was an effective way of teaching and working with students on their writing and whether the students would benefit from the Fantasy Workshop. As previously stated, in this chapter we share our insight on how we as teachers used a blended approach as we worked with our students. The main questions we had were: How can we work and involve all our students in the classroom with the use of a blended environment? Will the use of digital media in a blended environment help engage more students in the classroom? Will it give the students greater motivation to learn?

As teachers we went into this project believing that this process or strategy of combining different modes of delivery and learning (face-to-face and online) will help us reach out to all of our students. We wanted to trigger their interests especially in writing and in literature and to give them the opportunity to show the rest of the class their own strength. By working this way we believed that we could motivate the students so that everyone came out with a product they would be proud of.

We also wanted this project to make the students more active users of the technology as they worked through their own personal interests.

LEARNING

Before we share the outcomes of our project, we believe it is important to demonstrate how our work can be linked to the past literature on learning. Learning has through the years been defined in many ways and with different criteria for assessing whether learning has occurred. One thing that is common is that almost all theories of learning focus on the change in behavior as a result of new experiences and exercises. In her chapter on *Behavioral Views on Learning* in a book on *Educational Psychology,* Woolfolk (2001) discusses the concept of learning using other sources as follows:

In the broadest sense, learning occurs when experience causes a relatively permanent change in an individual`s knowledge or behavior (Hill, 2002). The change may be deliberate or unintentional, *for better or for worse. To qualify as learning, this change must be brought about by experience – by the interaction of a person with his or her environment (p. 200).*

Based on this definition, and also on work by Krokan (2012) one can conclude that there are three main types of explanatory models or theories that explain how we learn; behavioral theoretical models, cognitive learning theories, and constructivist learning theories. The behavioral view generally assumes that the outcome of learning is change of behavior and emphasizes the effect of external events on the individual (Woolfolk, 2001). Two of the most recognized names in behavioral learning theories are Pavlov for classical conditioning and Skinner for operant conditioning. Classical conditioning focuses on the learning of involuntary automatic responses associated with new stimuli while operant condition theory focuses on that which we can operate in our environment to affect the consequences. One learns to behave in certain ways based on the specific outcome in they have in mind.

Cognitive theories are based on our need to see and understand contexts. This means that context and understanding is emphasized. When we learn we must create mental images that can give understanding in a greater perspective. Learning is seen as an activity created by inner motivation which stimulates understanding (Krokan, 2012). Woolfolk (2001) also describes cognitive learning as "a general approach that views learning as an active mental process of acquiring, remembering, and using knowledge" (p.241). Constructivist learning theories emphasizes the active role of the learner in building understanding and making sense of information (Woolfolk, 2001). In practical pedagogy the use of group work, discussions and other forms of interaction is founded on the social constructivist paradigm. Knowledge is established through interaction with others. Learning in a paradigm like this happens by the initiative of the learner and his premises. (Krokan, 2012).

The way one views learning will influence teaching as well as the decision regarding the kind of digital tools to use in teaching in order to facilitate learning. Suppose one views learning as interactive, the theory that supports the use of interactive resources will be social constructivism. This way of thinking is supported by the way the interactive wall or page was used in our Fantasy Workshop. Lev Vygotsky has one of the most important voices in this direction. According to Vygotsky (1962) learning involves social processes. He sees learning as a result of interactions, in first hand social interactions. Vygotsky focused on the connections between people and the sociocultural context in which they act and interact in shared experiences. He believed that humans use tools that developed from a culture, such as speech and writing, to interact in their social environments and that the internalization of these tools leads to the development of higher thinking skills.

BLENDED LEARNING

The question is: Where does learning take place? The traditional mindset is that learning takes place in face-to-face settings. However, over the past number of years, we have come to understand that with the use of technology, learning can also occur in alternative environments such as online and with blended approaches. Blended learning has been hailed as the best environment. in his book *Blended learning*, the Danish pedagogic and writer Karsten Gynther (2005) describes blended learning in its broadest form as a way of teaching where one uses different pedagogical methods, different kinds of technology and mixes face-to-face teaching with online based teaching. Again, in her blog on Definition of Blended Learning which can be found on the Innosight Institute's webpage (see www.innosightinstitute.org), Staker (2011) describes blended learning as follows:

Blended learning involves a combination of online learning with an element of face-to-face.... Blended learning is any time a student learns at least in part at a supervised brick-and-mortar location away from home and at least in part through online delivery with some element of student control over time, place, path, and/or pace (par. 3-6).

Finally, on the itslearning website (see http://www.itslearning.net/blended-learning), Michael Horn (2013) defined blended learning as: "…the combination of online and face-to-face teaching. It promises to give more time with individual teachers and enable students to personalize their learning in and outside of school" (par. 2).

A good blended learning environment can be explained as a learning environment where students participate using both face-to-face classroom activities and online resources at the same time. Blended learning is considered the best environment because this environment provides students with a number of possibilities for learning and opportunities to for participation. For instance, students who learn best by interacting with the content on a number of occasions, have the opportunity to log on online to assess the same information they learned while in their face-to-face class. In the blended environment, the students who usually will not participate much in the traditional classroom will have an opportunity to assert themselves in the online environment, and will have a higher sense of participation. As such, the belief is that the blended learning environment could be a safer place for some students to learn; this environment provides students with a motivation to participate in class work and gives such students a good sense of achievement. Krokan (2012) notes that this kind of learning presents students with intrinsic motivation, rather than extrinsic motivation, causing students to be engaged in the learning process; which means that the students' actions in the learning environment will come from a genuine wish to learn something rather than just working because they have been asked to do. This makes the learning experience more pleasurable (Krokan, 2012).

As indicated previously the goal of a blended approach is to join the best aspects of both face-to- face and online instruction. Classroom time can be used to engage students in advanced interactive experiences. Meanwhile, the online portion of the course can provide students with multimedia-rich content at any time of the day and anywhere the student has internet access. In short, the blended approach provides variation in teaching and learning.

MOTIVATION AND VARIATION

Variation in teaching is important for students' motivation. In other words, students want practical and varied work as they learn. It makes them more motivated to do schoolwork. Regarding this area,Tong (2012, p. 4) cites the works of Marton and Booth's (1997) and Marton and Tsui (2004) as follows:

Marton and Booth's Theory of Variation is drawn from the phenomenographical research tradition. It argues that there is no single way to understand experience or think about a particular phenomenon; indeed there is considerable variation in people's discernment. In learning, individual students make sense of new concepts in different ways, according to their existing understandings and frameworks of knowledge. This requires teachers to engage closely with their students to grasp the variations in understandings and knowledge so they can take account of this diversity in structuring the learning activities in a lesson (Marton & Tsui, 2004).

Also, there must be a good balance between the variety of methods used. It is important that both practical and theoretical considerations are made in deciding on the methods to use as this will influence students' motivation to work. Motivation also comes from recognition; that is students are highly motivated to work, when they recognize features applied in teaching (such as the theme wall or page used in the Fantasy Workshop which bears similarity to Facebook and other social media channels). They become comfortable with the tools and find interest in the work.

The theme page we made was built using of different types of contributions (see figure 3). We included pictures, polls, video clips, documents and posts from both teachers and students. It was important that we built the page with varied information to motivate as many of our students as possible. We wanted the students to be interested in and curious about the project we posted on the page. We believed that the variation in the teaching materials will influence motivation and lead to a deeper level of learning. In addition, we wanted students to be interested enough to want to contribute at their own level of knowledge as the teaching was adapted to their level. Our hope was that by teaching this way, students will be able to find an inner motivation and an interest in the specific situation or lesson, leading to more contributions and more active learning as suggested by Dobson, Eggen, and Smith (2009).

FORMATIVE ASSESSMENT

Assessment is an evaluation of student outcomes as they learn from the teacher and also from learning. activities (Bloom, 1967, Lysne, 1999, Slemmen, 2009). Assessment can be done in a variety of formats. It could include for example answering questions in the lesson or homework tasks, meeting a set of criteria, performance in discussions, observations, short tests, assignments or projects. Formative assessments can be used to adjust teaching and/or learning. Dylan William (2011) states in his book *Embedded Formative Assessment* that "An assessment functions formatively to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have made in the absence of that evidence" (p. 43).

In the Fantasy Workshop under discussion in this study, there was a variation of formative assessment formats used to assess learning. On-going peer assessment was used by allowing the students to respond to each other's texts and contributions on the page. Students were also assessed based on their communication with the teachers. This form of assessment was a very important part of the project.

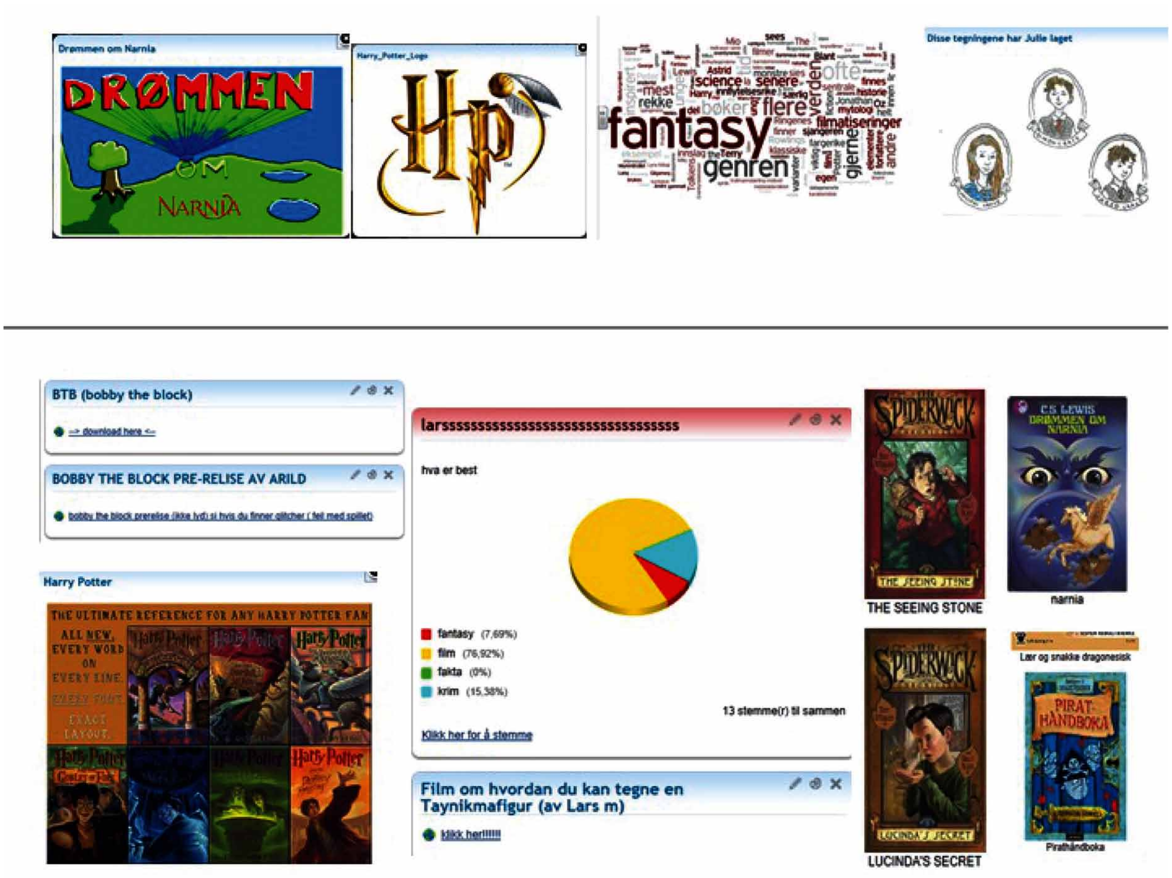
DIGITAL TRAINING MATERIALS AS SUPPORT FOR DIFFERENT STUDENT TYPES

Prior to introducing the use of digital media, it is important to evaluate how the media will support the different types of students with different learning styles and different intelligences in the classroom.

Different Student Types and Multiple Intelligence

Several factors are affected when one uses different digital media or information communication technologies (ICT) in the process of teaching and learning. One of the most important factors in the learning environment is the people that interact within the environment. A learning environment will always be complex and one will find all kinds of student types in it. As such when it comes to ICT and the different student types, students can be split into three different groups: the visual learner who will prefer to see things visually in order to understand, the auditory learner who prefers to hear before seeing and the kinetic learner who puts movement and body language high in their perception on what is to be learned (Eidsmo, 2005). Students may also be classified by identifying which learning styles suits them best or by identifying which type of intelligence strongly represented in them. No learning style or type of intelligence is better than the other, it just tells us that we learn, present, and use knowledge

Figure 3.



in many different ways. One kind of intelligence is stronger represented, but one type of intelligence does not rule out the others. "Each human being has a unique mix (or "profile") of strengths and weaknesses in the intelligences" (Gardner 2006, p. 11)

In 1983, Howard Gardner presented a theory that he called "multiple intelligence (MI)". This theory highlights the importance of seeing each student for who he or she is and not who he or she is expected to be. Since every student has their own mind they also learn, remember, understand and perform in different ways. Gardner divided intelligence into eight categories:

1. **Linguistic Intelligence:** The readers and writers who like to communicate through words.
2. **Logical–Mathematical Intelligence:** Logical and mathematical ability, as well as scientific ability.
3. **Spatial Intelligence:** The visual students, they are able to form a mental model of a spatial world and are able to maneuver and operate through it.
4. **Musical Intelligence:** The ones who sing, play, and make music. They have a good ear for musical shades and rhythm.
5. **Bodily–Kinesthetic Intelligence:** The ones who have the ability to solve problems using their whole body, or parts of their body. Characterized by high level of agility.
6. **Interpersonal Intelligence:** The ones with a strong ability to understand other people. They see how people work, what motivates

them and how to cooperate with others. Easy to work with and get to know.

7. **Intrapersonal Intelligence:** Often characterized by good self – knowledge. They will form an accurate, veridical model of oneself and are able to use the model to operate effectively in life.
8. **Naturalist Intelligence:** The ones who nurtures and relate information to one`s natural surroundings. They recognize and classify elements and patterns from nature.

"These intelligences constitute the ways in which individuals take in information, retain and manipulate that information, and demonstrate their understanding (or misunderstandings) to themselves and others" (Gardner and Veenema as cited in Gardner 2006, p. 76). Gardner argues that his theory of multiple intelligence is of great importance for educators. He wants the school system to recognize the many different and discrete facets of cognition, to acknowledge that people have different cognitive strengths and contrasting cognitive styles. He would like to see the school more individual – centered and says that the multifaceted view of intelligence has to be taken seriously.

An instructor will find all learner types in their classroom, and students with different strengths and intelligences. Therefore the need for the use of varied teaching methods and media or ICT to embrace all students. In our study, a good application involved the use of the interactive page used in the Fantasy workshop. In this environment, different students and all student types were embraced. For instance the theme page which was adapted for the students as they contributed content to their work allowed for the addition of images, sounds, and movement as required for all the different types of learners and their different intelligences.

THE STUDY-FANTASY WORKSHOP

Fantasy workshop is a subject for 6th grade students in Norwegian schools. The workshop typically involves the completion of a traditional project in reading and writing. This time around we decided to adjust our teaching and applied a blended approach to teaching and learning in the Fantasy workshop. The goal was to get the students to be familiar with the fantasy genre and to have them write a fantasy story. First of all, the students had to read fantasy literature to get to know the genre. The reading was done in reading circles; we divided them into groups of four or five students and they all had to read and discuss the same book.

In addition to the reading circles, an online environment was created using an LMS for students to work on the creation of a fantasy story. In the online environment, a resource page was created where students could gather relevant information for the project. It is important to note that the students worked collaboratively and with the teacher on this project. The students gathered all kinds of material they could find from a variety of sources that were relevant to the project. During this project, all participants including the teachers and students were encouraged to post the materials they found (trailers from fantasy movies, illustrations, facts about authors and pictures from the genre) to the online environment. The students were told that they could also make mobile phone videos about the books they had read and publish them on the theme page in the online environment. The online environment was accessible to everyone in the class and we could all log onto the page at any time. We used the school's library as well and made film reviews based on the books we located in the fantasy genre.

The Learning Management System (LMS)

The learning tool, itslearning, was used in this workshop. This LMS has several functions or tools which made it applicable to our work. As previously mentioned, we wanted to make an interactive resource page and it was important that the students could adapt the work around their own interests. With this LMS one can create content blocks and different tools such as polling tools and a theme page. The most popular function was the block which contained rich content. One could publish text, pictures and web links in the same block. The students posted YouTube links and wrote short messages or descriptions to explain the links to others who reviewed their work in the block. They also published pictures they had found or illustrations they made about their work in the block. Some even published parts of their fantasy texts and asked for feedback from their peers and the instructors in this area. The polling tools were used to ask for help from others as they made decisions regarding sections of their project such as the name of the hero in their story. They also made polls about the most popular books, films and writers others in the class had read or recommended.

The LMS also allowed us, the teachers, to add files to the learning environment. With this tool, we published everything we went through in class, like criteria, characteristics of the genre, schedule for the project, information about the project and examples of the project. In this way, everyone could find information whenever they wanted and it was always available to them. The theme page is a place where all the participants can find relevant notes, links, tests and so on. The teachers made decisions on who could assess and edit this page. We found it very safe to use this theme page as we knew who the contributors of the different parts were. In this way we were able to conduct the project with a rubric and students who did not follow the rubric were immediately noticed.

How the Project Developed

The students got a lot of inspiration from each other as they continuously posted their work in the online environment and became more active users of the LMS. The students got curious and wanted to find out what was new each day. They were eager to find out if someone had commented or answered their postings. This behavior towards this activity was very similar to that which can be experienced in social media channels such as Facebook. The students were familiar with this environment as they know “Facebook”. This made them comfortable and they were motivated, became engaged, and immersed themselves into the workshop as they created their work and communicated with each other and the instructors. The types of communication on the page showed us, the teachers, that the students were used to this way of communication on the internet. They got motivation from their classmates’ suggestions and wanted to do their best because they knew everybody could review their work and their contributions. The project also emphasized a need for them to show off their creative nature for others to see and notice their work. In this way, they learned a lot about the correct way to communicate on the internet and more importantly about the literature genre of fantasy. We saw students who would normally not do their work participate in class and submit excellent contributions on the page. This made them feel important and it lifted their status in the class. We saw qualities in students that we had never seen before; they had more creativity than we thought or had ever experienced or observed in the classroom. Both teachers and students came out of this with a new perspective.

While this arena or approach provided students with a lot of control and ownership over their work, it also ensured that they followed the class rules or rubric. We saw that this became a safe place to practice how to communicate on social media. Since the page was open only to the class and the teacher, we had a good overview and could weed out inappropriate comments or publications.

The Data

We worked with the "Fantasy workshop" for 5 weeks. During the middle and at the end of the project, we (the teachers) conducted a survey on student learning. The feedback we received suggested that the students enjoyed the project. The questions we asked were about how the students used the page, how often they used it, if they only looked at it or if they contributed on their own. We asked which tools they had used the most or if they had had any use for the page. Most of the survey questions were either of the yes/no-questions or multiple choice format. The survey was conducted in the itslearning learning system.

Outcomes from the Data: The feedback we received from our students suggested that the blended approach was a success and had a positive effect on student writing and reading of the fantasy genre. For instance, the majority of the students (76%) said that the feedback provided on the wall or theme page was of relevance to them and to the process of writing their own story. They indicated that they had good use of the page. The last question was an open-ended question where students were asked to indicate the ways in which they had used the online environment and whether the blended approach had been helpful to them. Here are a couple of the open-ended responses we received from the students:

I got lots of tips and ideas.

It has helped me to understand what others think, and I`ve been inspired by others.

I got help finding out what my magic passage should be, and finding a name for my fantasy city.

I posted my introduction and got help in how to go on with the story.

On the whole, we received good feedback from our students and observed that almost all students reached the goals set in the project. Student data showed that they did their best in reading the goals set in the project. Student data also showed that they did their best in reading books in groups, contributing on the theme page and writing a fantasy story, in groups or on their own. Everybody had a positive experience with working in this way and the students found it interesting and motivating.

For us, the teachers, the use of this blended approach and theme page in our work was new. We realized that our fantasy project was successful and presented students with a whole new perspective of the Fantasy genre. The students received much more complex knowledge about the fantasy genre, and of reading and writing. And above all, as teachers we observed important qualities in our students that did not stand out in the traditional face-to-face setting. In relating our processes and outcomes to the theory on different student types, we found that we were able to reach all student types in our classroom with this project. Different types of learning styles were met with the use of the LMS and online learning environment as a varied set of sensations were offered. The fact that students also got to form their contributions in their own way give them an arena where the pressure level to join was low. The project gave students the chance to receive and contribute with in-depth information as well as to receive and give positive feedback as they worked on reading and writing fantasy stories.

As teachers, we observed that our students were highly motivated during the process of the workshop. We believe this real life experience matches what students will ultimately need later in life. For instance, students learned such habits as collaboration, cooperation, critical thinking and providing constructive feedback.

RECOMMENDATIONS

Working with a project like this can be very valuable to teaching and learning and for students and teachers. The biggest value as we see it is how this project embraced students of all kinds. One important criterion that made this a success was that we created this learning activity around a theme and a genre. To engage the students in a big project like this, we will recommend that the teacher first formulates the project around a theme and one that will allow students to find relevant material easily.

For us, the Fantasy genre provided a perfect way to do this as one can easily find film trailers, pictures, stories and interviews mostly from the internet – a place where the students at this age spends a large amount of time anyway. Given the outcomes from our survey data and observations, we will highly recommend teachers to try out this blended approach to teaching and learning as such learning environments can be of high value to students. We know that many teachers use blogs in their teaching, and our idea is founded on the same thought where students have the possibility to work in a safe and interactive environment.

FUTURE RESEARCH DIRECTIONS

This topic of blended education continues to receive more and more attention in research. Researchers continue to encourage the use of digital resources at all levels of learning. The use of social media is also a big theme for researchers in higher levels of education. This approach can provide our students with a safe way for learning. As the number of people using social media is increasing every day, and the demographic of users includes more young students, we believe that if this form of teaching and learning is encouraged, it will be very useful at the K-12 level of education. The hope is that this chapter will provide K-12 teachers and researchers with insight on how they might implement a blended learning environment, the important factors to ensure a successful learning experience, and the outcomes of such processes.

Further research on this very complex field especially at the K-12 level is encouraged particularly as we know that the students even at young ages are now active users of the internet. Hence using this format will allow us to meet our students at their level and using techniques they are used to; techniques that allow them to be part of an interactive universe where they are engaged in higher levels of thinking. While the outcomes of project was positive, we will like to point out that challenges still exist on how best to blend face-to-face and online teaching at the K-12 level and in education in general.

CONCLUSION

The Fantasy workshop is an example of how blended teaching and learning can be used to engage and motivate young students in their classrooms. The project has an educational base but is also founded on the student`s interests and knowledge. These are what we see as important success criteria to this approach. As indicated previously, teachers need to work around a theme as they plan teaching and learning in an environment that combines face-to-face and online learning. Through relevant theory it is clear that working this way will give teachers the opportunity to challenge all kinds of students as they will be engaged at different levels that match their needs. Also such activities will be adapted to students' own reality. We can safely say that it might be almost impossible to reach such a success in a purely face-to-face classroom and without the integration of digital tools in an online environment. We see that the children of today are much more dependent on using their senses and getting stimuli on different levels and in different ways. Using interactive pages will help support the different student types and meet the challenges they struggle with from day to day in a face-to-face learning environment. The blended approach is an adaption that can be applied for teaching all students.

KEY TERMS AND DEFINITIONS

Blended Learning: A learning environment that manages to combine classroom teaching with online resources in a way that complements the learning situation.

Fantasy Workshop: A digital workshop where you go into the fantasy genre and world.

Interactive Page: Online based page where you can interact with other students and publish material in different forms.

It's Learning: Learning management system used at many schools in Norway

Theme Page: A web based page that is content specific, gives you insight on a theme.

This work was previously published in Practical Applications and Experiences in K-20 Blended Learning Environments edited by Lydia Kyei-Blankson and Esther Ntuli, pages 249-260, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

Chapter 19
Evaluating a Learning Management System to Support Classroom Teaching

Tiago França Melo de Lima
Federal University of Ouro Preto, Brazil

Thiago Nazareth dos Passos
Federal University of Ouro Preto, Brazil

ABSTRACT

New pedagogical approaches are required to prepare future professionals. The educational model must be in consonance with the information and communication technologies. They help to improve knowledge dissemination and reduce space and time limitations between teachers and students. They should also motivate students and stimulate communication and collaboration among students, improving the learning process. Currently, the Institute of Exact and Applied Sciences of the Federal University of Ouro Preto (IEAS/UFOP) has no institutionalized tools of information and communication for teaching support. This allows the identification of some problems and difficulties on the educational process, such as absence of a centralized way to provide and access didactic resources, unavailability of a good communication tool between teachers and students, and lack of easy access to academic performance information for self evaluation. This chapter presents the authors' experience in choosing and evaluating a Learning Management System (LMS) to support classroom teaching at the IEAS. The authors investigate how the use of a LMS may improve teaching in the following aspects: (1) availability of didactic resources; (2) class planning and following up; (3) teacher-student communication; (4) monitoring of the academic performance of students during the course; (5) collaboration among students.

INTRODUCTION

Technological development always brings changes to people's lives. The expansion of information and communication technologies and the dissemination of the Internet have created unprecedented connectivity. Besides, easiness to create and publish content is increasingly generating an enormous amount of information. Due to these and other factors, new paradigms of social inter-

DOI: 10.4018/978-1-4666-8246-7.ch019

actions are emerging and becoming necessary (Cardoso and Castells, 2006; Takahashi, 2000). Individual work is being replaced for teamwork, which is conducted collaboratively (Mills, 2003). Organizations are reformulating their strategies on conducting operational, business and administrative processes. This is happening regardless of the kind of organization - it could be an industry or service such as education, originating from private or government initiative (Castells, 1997; Castells, 1999).

Likewise, new pedagogical approaches are necessary to prepare future professionals (Anderson, 2008; Clark and Clark, 2009; Moran, 2000; Plomp, 2013). Learning is no longer individualized as well, and it is becoming collaborative, shared and collectively built (Duderstadt, 1997; Stahl et al., 2006). Therefore, education plays a new role aimed at continuous learning, information sharing and collective knowledge construction (Duderstadt, 1997; Laurillard et al., 2009; Plomp, 2013; Williamson, 2013).

The educational model must comply with information technologies - which can serve as cognitive 'prosthesis', helping increase socio-affective processes (Fagundes et al., 1999), disseminate knowledge, decrease limitations of time and space between teachers and students, and enhance learning through the use of multimedia / hypermedia resources (Morais & Cabrita, 2007). To promote the expected changes in educational process, information and communication technologies (ICTs) should be used as pedagogical tools to create an interactive environment that enables learners, faced with a problem, to investigate, raise hypothesis, test and refine their ideas, thereby building their own knowledge according to their individual learning style (Vieira, 1999). Students are no longer mere information receptors, they are rather builders of their own knowledge (Lê, 2002; Moran, 2003).

As these technologies allow the improvement of information communication and production, a first proposal would be to think about the processes of storing and organizing information and communication as ways to enhance the teaching-learning process. The space extends beyond the classroom, into the virtual space (Moran, 2003). It brings the educational process closer to students' reality, once they already use these technologies in their everyday lives.

In this context, the teaching-learning process can be supported by many resources provided by ICTs. For example, Learning Management Systems (LMS) allow the integration of functionalities related to communication and content distribution. Although in general they are applied to distance learning, they could also be used to support classroom teaching, for example, by helping teachers manage didactic resources, facilitating communication with students, among other things.

In this sense, many institutions around the world use ICTs and the Internet to improve the education. Several e-learning (electronic learning) and b-learning (blended learning) initiatives have been developed. Many learning management systems have been created and used to support e-learning and b-learning activities (Hewagamage, 2007; Kalogiannakis, 2004; Ishitani et al., 2006; Ishitani 2009; Morais & Cabrita, 2007; Mortera-Gutiérrez, 2006; Silva et al. 2008, Wang et al. 2007). Some examples are: Moodle, LearnLoop, TelEduc, AulaNet, BlackBoard, WebCT.

Currently, the Institute of Exact and Applied Sciences (IEAS) of the Federal University of Ouro Preto has many problems and difficulties related to the educational process, such as the lack of a centralized way to provide didactic resources for students; absence of a good communication tool between teachers and students; need of fast and easy access to information on students' academic performance for self-assessment.

So, we propose the use of a learning management system to support classroom teaching at the Institute of Exact and Applied Sciences. We investigated and argued about how the use of a LMS can improve classroom teaching in the following aspects: (1) availability of teaching resources; (2) class planning and following up; (3) teacher-student communication; (4) monitoring of students' academic performance during the course; (5) collaboration among students.

This chapter presents the investigation and evaluation process of a LMS to support classroom teaching at the Institute of Exact and Applied Sciences. Initially, a diagnosis of the current reality of IEAS was made to identify teachers and students' main needs. Questionnaires and interviews were used to collect data. Then, based on the results, a comparative analysis of some LMSs indicated the Moodle platform as the best solution to address the institute's needs. Finally, the LMS chosen was deployed and evaluated.

The chapter is organized as follows: Section Learning Management Systems introduces some basic concepts about distance learning (e-learning and b-learning), learning management systems, and related works including some successfully examples of the use of LMS. Section Evaluating the Moodle Platform presents the development of work, starting with diagnosis, when the institute's needs were identified, following by analysis of LMS tools and choice of the Moodle platform, and finally, outcomes are shown and discussed. Lastly, conclusions and next steps are presented.

LEARNING MANAGEMENT SYSTEMS

In the Information Society, there is a need for constant contact with information. We frequently use information and communication technologies as tools to acquire information and knowledge for personal and professional development.

A definition for distance education is: "institution-based, formal education where the learning group is separated, and where interactive telecommunications systems are used to connect learners, resources, and instructors" (Schlosser & Simonson, 2009, p. 1). Distance learning can be defined as the teaching-learning process in which teachers and students are not together physically, but they can be connected by technologies such as the Internet (Keegan, 1996). Other media like television and radio can also be used. The media used before the Internet favored communication in a single direction: from teacher to students. Information was only transmitted, but there was almost no feedback. The Web allowed efficient bidirectional communication through the use of tools such as e-mails, instant messages, chats, forums. It enables more interaction between students and teachers during the teaching-learning process and favors collaborative learning. Thus, students are not just information receptors, they have become active participants of their own knowledge construction (Lê, 2002; Behens, 2007; Moran, 2007). Although collaborative learning is not restricted to the Web, the use of such resources enhances the results. Further discussions about distance education definitions, concepts and applications can be found in Moore (2013), Schlosser & Simonson (2009).

Computer-assisted learning (CAL) created new learning contexts, which require the use of new pedagogical approaches (Stahl, 2006). Examples of CAL applications and evaluations can be found in many areas and places (Millde-Luthander et al., 2012; Ecalle et al., 2013; Kalet et al. 2012; Schifferdecker et al., 2012; Veneri, 2011; Huang et al., 2012; Lai et al., 2013; Belal, 2011; Schittek et al., 2001; Shaw and Marlow, 1999). Students are not only receivers of content, they develop their own knowledge and manage their learning. Similarly, computers are not mere tools that teach something, but tools through which students develop things and, moreover, the learning process occurs when these devices are used to perform activities. Furthermore, by incorporating the Internet, we have been able to conceptualize e-learning.

The concept of e-learning refers to the use of information and communication technologies to provide resources and tools to improve knowledge acquisition and learning performance (Rosenberg, 2002). On e-learning both communication and distribution of didactic resources occur online. The paradigm shift is inevitable: the teacher is no longer the main source of information and responsible to pass on knowledge. The Internet plays a very important role as a source of information and a means for knowledge construction (Valente, 1995). In this context, teachers need to develop a new way to teach and build a new image of their work: reducing their interference and increasing students' responsibility for knowledge acquisition. Thus, teachers should use new approaches and strategies to teach, acting as tutors, and becoming learning mediators or managers, with new abilities and responsibilities (Almeida 2003; Kalogiannakis, 2004). E-learning allows students to learn at their own pace and offers benefits such as access to information in a nonlinear way and reduction of space and time limitations. This is another step in the evolution of distance learning, whose main specificity is the use of computers and the Internet as predominant means to promote learning (Santos et al., 2010). There is no consensus on e-learning definition - further discussions about this topic can be found in Andrews & Haythornthwaite (2007), Gomes (2005), Kahiigi (2007), Tsai & Machado (2002), Zhang & Nunamaker (2003).

E-learning does not exclude the traditional educational model, as both models can be combined. B-learning can be understood as a mixed learning. It is a combination of classroom teaching and distance learning, mediated over the Internet (Bonk & Graham, 2012; Sharma, 2010). Blended learning systems combine face-to-face instruction with computer-mediated instruction (Graham, 2006). This hybrid model arises as a complement and an extension of traditional and online learning. It has two distinct goals: (1) to minimize the face-to-face component, reducing the traditional model of education by performing most activities remotely, and; (2) to complement the face-to-face component – the remote element attempts to facilitate access to contents and improve communication and interaction between students and teachers, even outside the classroom (Adão and Bernardino, 2003).

Thus, b-learning aims to provide greater efficiency and effectiveness to the traditional teaching model by using the remote component. The face-to-face environment is complemented by online activities, e.g. online discussions, quizzes, assignments, submission of assignments, engagement in collaborative activities (Duhaney, 2004). Moran (2007) emphasizes that the virtual environment can be remotely used by students for research activities (individually or in groups), discussions, as well as to solve doubts, delve into subjects covered and studies of more complex contents. He also emphasizes that, for quality education, these two spaces (virtual and presential) must be integrated. This opens up a range of possibilities in education and has several implications such as a more dynamic learning process, need for students to learn more independently and teachers to become facilitators and managers of students' learning. Blended learning also involves many discussions about its definition and related concepts (Graham, 2006; Graham et al. 2003; Kim, 2007; Picciano & Dziuban, 2007).

While traditional distance learning uses media such as radio and television to provide information, e-learning and b-learning use the Internet. However, merely using the Internet does not suffice. A tool which allows the management of learning processes is necessary, integrating and providing teaching resources, and also offering communication tools. To that effect, learning management systems are good alternatives.

Accordingly to the concept of virtualization (Lévy, 1996), virtual learning environments (VLE) can be viewed as virtual classrooms accessed over the Internet. They are social spaces, formed by social-cognitive interactions around a subject of knowledge (Valentini & Soares, 2010). Moreover, they use the cyberspace to convey content and enable interaction among actors of the educational process – aiming to facilitate or promote learning

(Pereira, 2007). Dillenbourg et al. (2002) identify some features that characterize virtual learning environments: (1) they are designed information space, (2) they are social space, where educational interactions occur, (3) the virtual space is explicity represented, ranging from text to 3D immersive worlds, (4) the virtual space is co-constructed by students; (5) they are not restricted to distance education, and could also enrich classroom activities, (6) they integrate heterogeneous technologies and multiple pedagogical approaches, (7) most virtual environments overlap with physical environments.

According to Weller (2007), a virtual learning environment is Web-based system designed to support teaching and learning, providing features and tools for communication, performing tasks and assessments, administration of courses (contents, students). A VLE is a software system that facilitates the e-learning. Such systems are also called learning management system (LMS), course management system (CMS), learning content management system (LCMS), managed learning environment (MLE), learning support system (LSS) or learning platform (LP) (Martin & Serrano-Fernández, 2009). Further discussion about definitions and terminology can be found in Moore et al. (2011), Paulsen (2002).

Thus, a LMS is intended to integrate resources in a common place, such as a virtual classroom as well as to help educators communicate with students and manage contents and courses. There are many free (Moodle, LearnLoop, TelEduc, LearningSpace) and commercial (BlackBoard, AulaNet, WebCT) learning management systems available with several resources and characteristics. In this work, the following tools were analyzed: Moodle, Teleduc, AulaNet, LearnLoop. All of them are Web-based applications and can be accessed by students and teachers using a Web browser. Despite the fact that they present several distinct characteristics, in general, learning management systems have many similar resources and tools, which can be grouped according to their functionality, as described below and presented in Table 1.

Table 1. Resources and tools grouped by functionality

Time Control	• Schedule • Event reminders
Evaluation	• Exercises • Projects and Research • Questionnaires
Communication	• Chat • Electronic mail • Forum • Messages (synchronous and asynchronous)
Personal Space	• Personal homepage • Blog • Wiki
Management of Activities and Didactic Resources	• Virtual drive • Interaction map statistics • Notes • Groups • Glossary
Platform Support	• Search engines • FAQ • User support • Virtual communities (users and developers)
Platform Maintainability and Development	• Plug-ins / Modules • SCORM (Sharable Content Reference Model)

- **Time Control:** helps organize time of events and activities during a course.
- **Evaluation:** allows the creation of evaluation activities and methods to verify the knowledge about a given subject.
- **Communication:** allows synchronous and asynchronous communication among users (students and teachers).
- **Personal Space:** enables users to create an individual profile and a public space to publish information and share contents.
- **Management of Activities and Didactic Resources:** allows the creation and management of didactic resources.
- **Platform Support:** helps users interact with the learning management system.
- **Platform Maintenance and Development:** supports the maintenance and development of learning management systems and courses.

Some of the advantages related to the use of learning management systems are: the possibility of grouping didactic resources in a single place; the ability to remotely perform activities and assessments; the capability to communicate synchronously and asynchronously; the potential to encourage collaboration; and support to manage processes in a course. Belloni (2002) highlights some of the advantages: (1) any time - possibility to attend a course at any time; (2) any place - ability to conduct and participate in a course at any place without the need of a physical space; (3) self-paced - the environment allows learners to set their own learning pace; (4) collaborative learning - students can learn from each other through group assignments, forums, debates and exchange knowledge by chat; (5) self-learning: students can learn autonomously.

However, the use of learning management systems alone does not suffice. The quality of the educational process depends on the involvement and analysis of technological, human and organizational dimensions. The technological dimension relates to the technical analysis of computers, devices, systems and network infrastructure needed to properly run the LMS. The human dimension refers to the people involved, such as students, teachers, tutors, and technical support. Finally, the organizational dimension refers the institution's educational processes (Neto & Takaoka, 2008).

Thereby, choosing the learning management system is an initial factor, yet, it is a very important one. This is directly related to the success or failure of its use in the educational process. In this work, the systems presented below were analyzed. They are used in many higher educational institutions in Brazil and worldwide.

The Moodle (Modular Object-Oriented Dynamic Learning Environment) platform is an open-source tool that allows the creation and management of courses. It offers many functionalities such as forum, chat, wiki, and calendar. In addition, it has a large user community and is currently used by many institutions around the world (Silva et al., 2008; Stewart, 2007).

Developed at Nucleus of Informatics Applied to Education of Unicamp (Campinas University – Brazil), the Teleduc is a free software whose goal is to provide teachers with a computational environment that enables them to prepare and monitor courses over the Web (Franco et al., 2003; Rocha, 2002; Rocha, 2003).

AulaNet is a collaborative Web-based learning environment. It was developed at the Software Engineering Laboratory of the Catholic University of Rio de Janeiro (Fucks et al., 1999; Fucks, 2000;).

LearnLoop is another open-source project that is used by many universities around the world. It has several resources such as synchronous and asynchronous communication tools, course management features and collaborative learning (Brugger et al, 2005).

The environments were analyzed in terms of resources and tools offered and, then, the one considered most suitable to meet the needs of IEAS was chosen. This analysis included technological and learning aspects. The Moodle stood out among others for offering more resources and tools, as well as for its larger user community. In addition, its acquisition and use are free of charge, as are all of its software requirements. Also, customizations and development of new features can be directly implemented by changing its source code. Finally, it has a large community of users, contributors and developers, from whom it is possible to get help and technical support.

Related Works

Learning Management Systems are currently being used in several higher education institutions in Brazil and worldwide to manage and support classroom courses and obtain more effective control of information and processes.

One example is study developed at the Institute of Informatics of the Catholic University of Minas Gerais, where the LearnLoop was used to assist teachers and students. In this study, the use of LMS was positively accepted by students and teachers, mainly in computer science area (Brugger et al., 2005).

In another work, developed at the CENSA Institute of Higher Education (ISECENSA), in addition to a good acceptance rate, it was possible to observe some improvement on students' learning performance. The Moodle platform was adopted to reinforce the classroom teaching in a mathematics course of undergraduate degree in Production Engineering. From surveys conducted in the study, authors noted that there was a good level of user satisfaction and that students improved their learning performance. The project was initially conducted as a case study was later adopted in other subjects (Silva et al., 2008).

At the Amazon Institute of Higher Education (IESAM), the TelEduc was used between 2004 and 2006 but was later replaced by the Moodle. It was used to train teachers and to support classroom learning. The platform was evaluated to identify improvements brought by its use. It was observed that students had better learning performance due to the adoption of multimedia resources, which made it easier for them to understand contents. Another positive aspect was the interactivity provided by tools such as chats and forums, which allowed discussion about issues related to courses. But research also showed that these advantages are directly connected to strategies used by teachers. Authors concluded that the Moodle helped teachers apply contents and students improve learning. In this work, the results suggest that the Moodle platform brought greater benefits than the TelEduc, which was used earlier (Batista & Cleidson, 2010).

Another study, conducted at the University of Brasilia (UnB), aimed to analyze the use of the Moodle in undergraduate degree in Librarianship. Usability tests, questionnaires and interviews were applied to evaluate the interaction with the environment and identify the benefits for classroom teaching. Results showed that students were favorable to the innovations introduced by the Moodle. The perceived advantages related to the use of tools and resources include better interaction between students and teachers, online submission of assessments and course activities (e.g. exercises, projects), easy access to additional resources. Teachers acknowledged the Moodle as a platform that makes it easier to provide didactic resources and allows communication with students outside class time. However, due to some difficulties and lack of knowledge, it was not efficiently used by teachers. Thereby, the author highlights that the deployment of the platform does not suffice, and ways to support, guide, help and encourage future users must be taken into account (Yunoki, 2009).

Morais and Cabrita (2007) analyzed mainly the communication and interaction perspectives on using a LMS in a b-learning context. They argue that a LMS favors a more active and autonomous participation of students. The Blackboard was used by undergraduate students of communication area. The results suggest that use of LMS brought improvements to interaction among students and between them and the teacher. Social interaction between students outpaced the physical boudaries of the school, reaching new dimensions in the virtual environment. In another study, Uzum and Senturk (2010) compared performance and attitudes of students when using two course delivery methods, and found that the blended course delivery method was more successful than face to face.

Bri et al. (2009) analyzed the following aspects of learning management systems: level of popularity, resources provided, utilization in Spanish universities, performance evaluation. The tools investigated were Moodle, Sakai, Blackboard, WebCT. The results indicated the Moodle platform as the better tool. Another comparative analysis was made by Gabardo et al. (2010). They analyzed several platforms (TelEduc, AulaNet, Amadeus, Eureka, Moodle, e-Proinfo, Learning Space, WebCT) based on the following criteria: distribution, pedagogical principles, collaborative learning, interactivity, multimedia, usability, accessibility. The results suggest that platforms present gaps in their construction and / or presentation. Some disparities were found regarding interactivity and availability of tools for collaborative learning. Some platforms, despite emphasizing the possibility of using multimedia systems, information about these features are not clearly available. Accessibility is the least contemplated issue. Therefore, authors argue that platforms are short of what they could represent in innovation.

The Moodle was also chosen in a study developed by Aydin and Tirkes (2010). They analyzed and compared some open source learning management systems (Moodle, ATutor, DOKEOS, OLAT). They highlight the advantages of using an open source software (OSS), such as the decreasing of dependency risk and associated costs, higher flexibility and frequency of updates when compared to proprietary software, security, and low cost. Despite all the tools offer sufficient basic functions for their use as LMS, the Moodle excelled among which. It presented advantages practically in all of the features compared. Moreover, its modular design leads to a great flexibility, its interface has greater usability, and its ease of installation and maintenance has led to enhance and spread their user community. Other analyzes can be found in Aberdour (2007), Georgiakakis et al. (2005), Graf & List (2005), Ozdamli (2007), Uzunboylu et al. (2006), Suri & Schuhmacher (2008), Hussain et al. (2011), Fertalj et al. (2006).

EVALUATING THE MOODLE PLATFORM

Analyzing and Choosing the Learning Management System

In this section we described the steps carried out to deploy a learning management system to support classroom teaching at the Institute of Exact and Applied Sciences of the Federal University of Ouro Preto. In a project of this nature, an initial challenge is to choose a tool that is appropriate to the institute's context and meets the needs of students and teachers.

In this sense, to guide the analysis, evaluation and selection of a learning management system, were initially defined the following aspects, which should bring either benefits or improvements to the academic community: (1) availability of didactic resources, (2) class planning and following up, (3) communication between teachers and students, (4) monitoring of students' academic performance during the course, (5) collaboration among students.

After identifying the basic guidelines to analyze and choose the most suitable tool, the following steps were taken: (1) diagnosis, (2) comparative analysis of learning management systems, (3) deployment, and (4) evaluation of chosen LMS. The diagnosis was initially conducted to identify main problems and demands of the institute and identify needs that the learning management system should meet. Based on the diagnosis results, a comparative analysis of learning management systems was made, in order

Table 2. Population and sample of diagnosis research

Students			
Course	**Population**	**Sample**	**Rate**
Computer Engineering	157	13	8.28%
Electrical Engineering	170	19	11.18%
Production Engineering	318	37	11.64%
Information Systems	258	41	15.89%
Total	903	110	12.18%
Teachers			
Teachers	59	19	32.20%

to select the most suitable system to meet the institute's needs. Then, the system was deployed and evaluated with a user groups composed of students and teachers.

A diagnosis was initially made to identify IEAS's current reality as well as the main needs of teachers and students. Based on the results, some LMS were analyzed. Data was collected by means of questionnaires, sent to teachers and students. The GoogleDocs platform was used to create questionnaires and manage the research, which happened in October 2012. The population and sample (response rate) are presented in Table 2.

The questionnaire was designed and organized according to the five aspects mentioned above (availability of didactic resources, class planning and following, communication between teachers and students, monitoring of students' academic performance during the course, collaboration among students). They included both open-ended questions as closed, of qualitative and quantitative nature. Thus, we identified problems related to each of these topics. Considering the results obtained, a comparative analysis of some learning management systems was made.

To make a comparative analysis of the learning management systems, their main features and resources were identified. The diagnosis outcomes helped define some criteria that were used on the comparison, such as: centralized publishing and delivering of didactic contents, synchronously and asynchronously communication, collaborative learning, and academic performance monitoring. Moreover, some case studies about the use of these tools were considered and also helped select the most suitable tool to address the needs of IEAS. All of the studied LMS are based on the LAMP (Linux, Apache, MySQL, PHP) platform. As a result, the Moodle platform was chosen to be deployed and evaluated.

After the Moodle was chosen as the platform to be used, the next step was to deploy it. An important issue before the installation and configuration was to identify hardware and software requirements (a Web server with PHP and MySQL database). It was installed and configured on a computer with the following configuration: Intel Dual core 2.8 GHz, 2 Gb RAM, 500 Gb HD. The Debian distribution of Linux operation system, with Apache Web server, PHP and MySQL were used to install the platform.

Finally, the following step was to evaluate the Moodle with a group of users. IEAS Teachers and students were invited to participate. The volunteers were organized in two groups: teachers and students. The evaluation with users was made from a brief training and use of the platform and a survey for data collecting.

During the training, both user groups were asked to perform some activities using the many resources provided by the platform. These activities were designed based on the aspects which were being investigated (availability of didactic resources, class planning and following up, communication between teachers and students, monitoring of students' academic performance during the course, collaboration among students). The group composed of students used the Moodle according to their viewpoint, performing activities such as accessing an educational resource (e.g. an article), creating an event (e.g. a test) on the calendar, sending an exercise, participating in a forum. In turn, the group composed of teachers performed activities such as planning a course, sharing teaching resources, creating educational activities (e.g. exercises and discussion forums), posting information and notices related to the course. After the training, each user group answered a questionnaire. The analyses were made considering the data collected in this step together with diagnosis outcomes. Some of the results obtained are presented in following section.

Results

This section presents the results obtained from the diagnosis. The analysis sought to identify limitations and shortcomings related to teaching activities in the institute, and to evaluate the improvements and advantages brought through the use of a learning management system as a tool to support classroom teaching. To facilitate identification, results are shown grouped and synthesized considering acceptance level, perceived benefits and improvements achieved considering the use of the Moodle platform. In addition, the results were organized and presented in accordance with the following points investigated: planning and following up of courses, provision of teaching resources, communication between teachers and students; monitoring of students performance, collaboration among students.

Planning and Following Up of Courses

Planning and following up of courses refers to the activity of planning and organizing the way a subject will be held, activities set, as well as the schedule and contents of classes. This activity is very important for teachers and students.

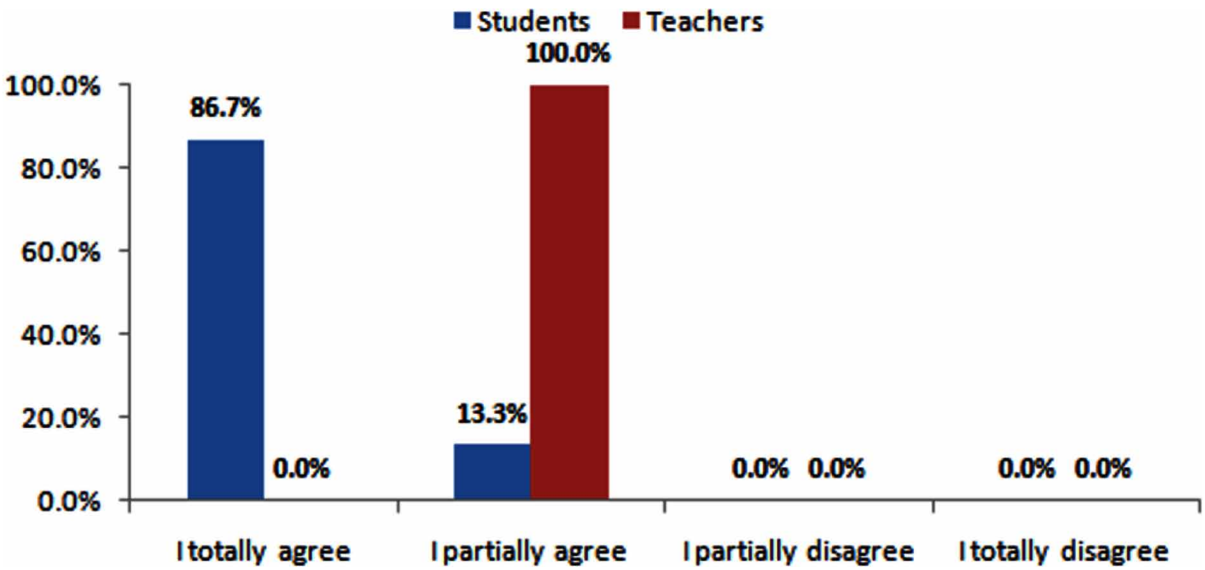
Planning lessons and activities of a course is a fundamental activity for teachers. In turn, the monitoring of lessons and activities (course schedule) is essential for students. The diagnosis identified that most teachers prepare a course plan, although a few do not. Also, it was identified that this information is often made available only in the classroom and in a non-digitalized form. Thus, it cannot be easily and remotely accessed by students. When information was digitally made available, the means used were mainly e-mail, websites and discussion groups. Teachers rarely used LMS. This variety of methods used by teachers prevents or makes it difficult for students to access and follow up on course planning. Most electronic media used had positive evaluations, showing the interest of participants in using digital media for this purpose. For good performance, it is essential that students be able to keep up with course activities effectively and efficiently.

The Moodle has many features that facilitate the planning and monitoring of lessons and activities of a course. After using it, it was possible to identify great acceptance of the tool among students and teachers. Virtually all participants agreed that the use of the platform would improve students' academic performance (Figure 1).

Availability of Didactic Resources

Availability of didactic resources refers to the provision of teaching materials such as articles, books, tutorials, documents, slideshows, that is, any support material which could be used by students during the course. Currently, most IEAS

Figure 1. The use of the Moodle platform improves efficiency in following up on courses and helps improve students' performance



teachers provide these resources, although this is not done by some of them (according to the data collected).

Investigation results indicate that the classroom is the main media used by teachers to make didactic resources available for students. Photocopies and e-mails are also frequently used, while websites and LMS are rarely used. But, in general, Web-based media were well evaluated by teachers and students with the purpose of making resources available, as shown in Figure 2.

Before the training, few people were familiar with the Moodle platform. After the training, it was possible to visualize a significant increase of positive evaluations related to the tool to make didactic resources available. Tools like e-mails and discussion groups, currently used for this purpose, were well evaluated on the diagnosis. The Moodle platform has many features that allow the management of a diverse and large volume of documents. There are tools to support teachers in storing and delivering materials, so they can be easily accessed by students. After being used, the Moodle platform was chosen as the best solution to this task (Figure 3).

Communication between Teachers and Students

Proper communication between teachers and students is critical to achieve an effective and efficient teaching-learning process. Only with facilitated communication can students clarify doubts about class contents, make questions, get advice about other learning resources, show interest and be oriented for further studies in a particular field.

The diagnosis showed that, currently, communication between students and teachers occurs mainly in the teacher's room and via e-mail. These forms of communication were well assessed. Other communication tools such as instant messages and groups are rarely used. However, after using some of the communication features offered by the Moodle, there was a positive change in how the communication means were evaluated. Due to the possibility of synchronous and asynchronous communication with teachers and with other students, the platform was very well evaluated and its use was recommended here as well.

Figure 2. Media use rates to make didactic resources available

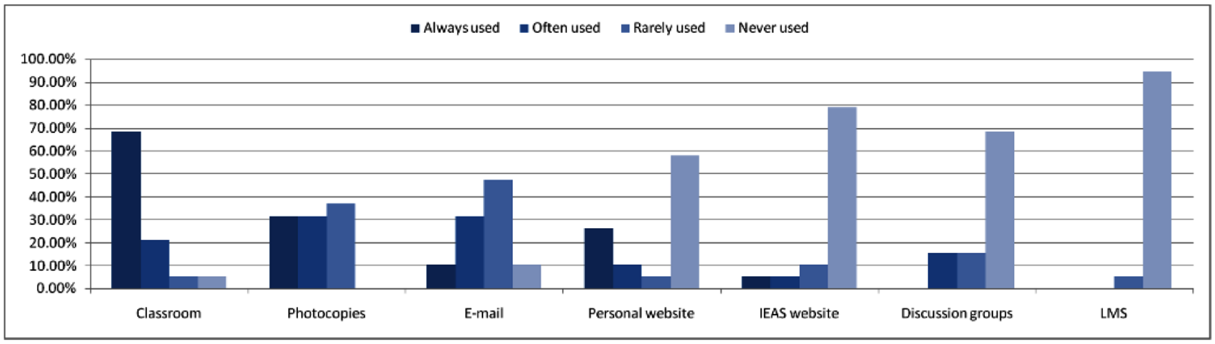


Figure 3. Media to share and make didactic resources available

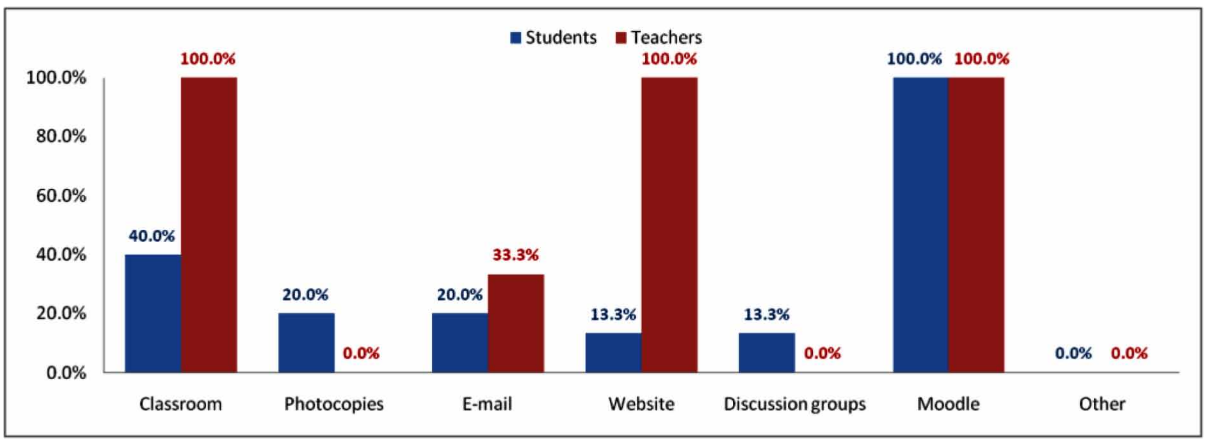


Monitoring Students' Academic Performance

The assessment of students' performance during the course is based on information such as grades and attendance. Access to this information is essential to enable students to make self-assessments of their performance. As for this topic, outcomes identified some contradiction between the answers given by students and teachers in regard to the availability this kind of information and means used to make it available (Figure 4).

After the training, students and teachers recognized that the Moodle is an excellent alternative to share academic information with students, allowing them to evaluate and monitor their own performance.

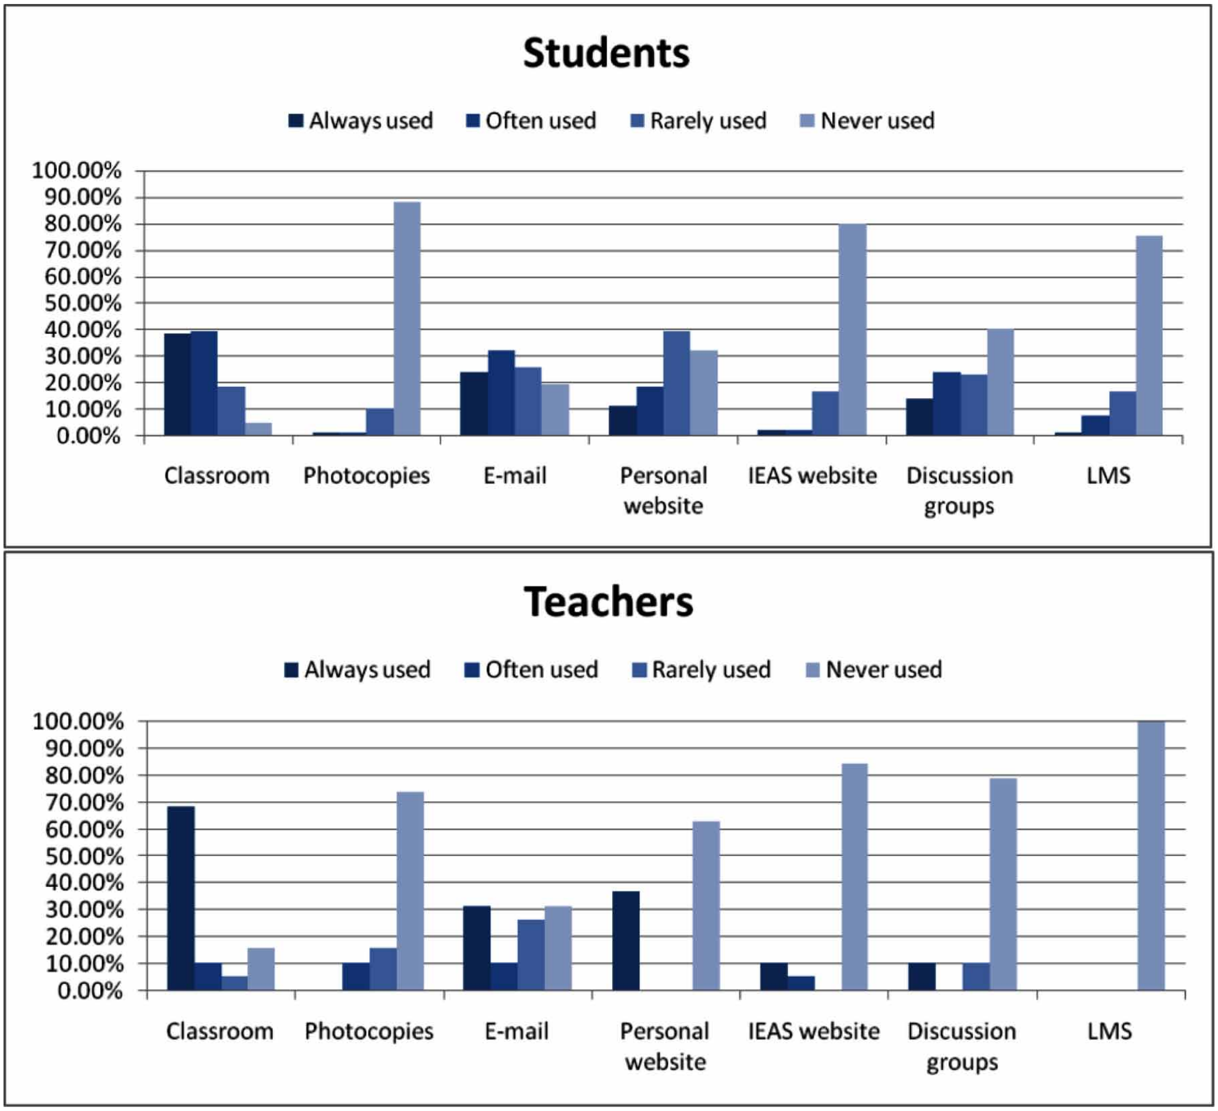
Collaboration among Students

In general, teachers do not use tools that facilitate collaboration among students. During the training, it was possible to present many resources of the Moodle which allow cooperative work and facilitate collaborative learning. Students and teachers seemed to be quite excited to use these resources.

SOLUTIONS AND RECOMMENDATIONS

The Moodle learning management system was deployed at IEAS. As described, this choice was based on the following factors: institute's needs identified in the diagnosis, comparative analysis

Figure 4. Media use rates to provide academic performance information

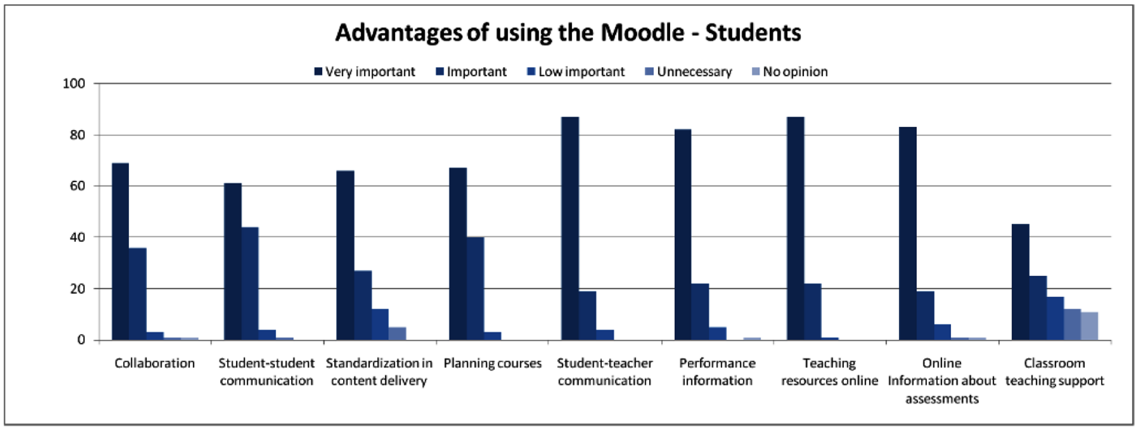


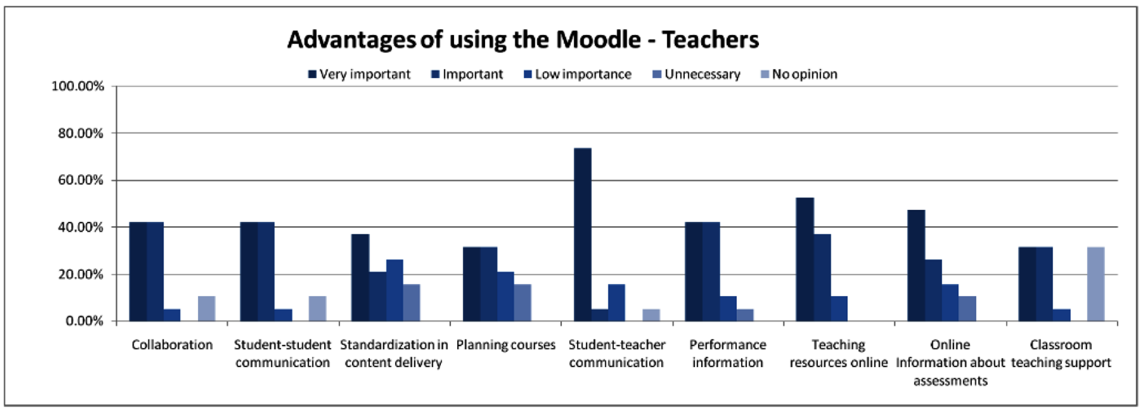
of some tools, and assessment of successful experiences.

First, it was possible to verify that only few students had knowledge or experience with learning management systems. This type of tool was rarely used by IEAS teachers. Among the systems analyzed, the Moodle stood out as the best one known. However, at the diagnosis phase, students and teachers agreed that improvements obtained by using a LMS to support classroom teaching are very important. Part of these data is shown in Figure 5.

Regarding the interest of students and teachers in adopting the LMS, in diagnosis step, most of them answered that they would like to use a system, but did not mention which one. However, after the training and evaluation steps, the Moodle was well accepted by participants. As for the Moodle's tools and resources, we also analyzed issues related to easiness of use and potential

Figure 5. Advantages of using the Moodle for students and teachers





improvements to students' performance. Most students and teachers recommended its adoption as a tool to support classroom teaching at IEAS, despite some difficulties faced by a few of them, which could be resolved with training.

These results suggest that the IEAS academic community had a great interest in using learning management systems to support classroom teaching. Also, it was possible to observe that the Moodle platform was well accepted and people were pleased to use its resources and tools. Thus, adopting the platform could bring teaching improvements, as well as improvement in the learning process for students and teachers at IEAS.

FUTURE RESEARCH DIRECTIONS

Next steps of research include an investigation about the current use of the Moodle platform at the Federal University of Ouro Preto. A set of questionnaires will be applied to collect data and measure the use of LMS to support classroom teaching and to evaluate the perceived benefits from its use. Then, a group of teachers will be selected to attend a training course on the Moodle. During this study, teachers and students will be accompanied and Moodle's use will be monitored. Thus, we will make a comparative analyzes between some subjects in which the Moodle was used versus others in which it was not.

CONCLUSION

Technological evolution and the growth of the Internet have considerably changed the teaching-learning process. A paradigm shift in education is necessary in order to improve learning. Advances in information and communication technologies have given rise to many platforms to support distance learning. Most of them can also be used to support classroom teaching. But to effectively get the possible benefits, it is essential to plan and choose the most suitable tool, considering the context in which it will be adopted. In addition, not only technological aspects should be taken into account, but also the organizational and human dimensions.

Some proposals for use learning management systems, like use them only to make available text and activities, are a simple replication of the traditional education conception to virtual environments. The learning remains centered on the teacher, the single holder of knowledge and responsible for passing it (Moran, 2003). Thus, the simple utilization of a learning management system does not means a modern teaching (Ishitani, 2009) and does not guarantee effectiveness per se (Dillenbourg et al., 2002). However, as suggested by Duhaney (2004), the use of blended learning activities should be introduced gradually - "instructors can begin the course in the traditional face-to-face environment and introduce the different strategies/techniques and technology as they become more comfortable using them and are able to determine how their use will help students achieve the learning targets" (Duhaney, 2004, p. 37). With these tools, the space extends from classroom to the virtual, the time to receive or send information expands for anytime and any day, and the communication process occurs in the classroom, on the Internet, email, chat, forum. As the relationship with time, space and communication with students are modifying, the teacher's role is changing. It is a role that combines attributions of a "conventional teacher" with others like encourage and manage research activities, stimulate and motivate students, promoting their autonomy on learning process (Moran, 2000).

Although some researchers have not found significant difference in course achievement between blended and face-to-face approaches (Tang & Byrne, 2007; Delialioglu & Yildirim, 2008), many others emphasized that the blended learning provides improvements in learning outcomes, sense of community, and satisfaction of students and teachers (Schrum et al., 2007; Amrein-Beardsley et al., 2007; Smith, 2005; Lonn & Teasley, 2009; López-Pérez et al., 2011; Garrison & Kanuka, 2004; Rovai & Jordan, 2004; Collopy & Arnold, 2009; Wingard, 2004). There are many reasons for using blended learning, such as: improves pedagogical richness, increases access/flexibility, favors access to knowledge, promotes social interactions (Graham et al., 2003; Osguthorpe & Graham, 2003). Although the learning environment is changed, the way that students learn does not change (Uzun & Senturk, 2010). While technology can be strategically used to deliver instructional content, the focus should be on the instructional uses rather than the technology itself (Pang, 2009).

This chapter presented the adoption of a learning management system to support classroom learning at the Institute of Exact and Applied Science of a Brazilian university. Based on the results, it was possible to observe that using the Moodle platform will benefit the teaching-learning process in several ways. Once the main immediate advantages of the use of the Moodle were identified, the next stage of the project is to evaluate the use of the platform in some courses over a one-year period. This will produce richer results in relation to the human and organizational dimensions.

Chapter 20

Blogs in Teacher Education:
Knowledge Sharing among Pre-Service Teachers on a Group Course Blog

Peggy Semingson
The University of Texas – Arlington, USA

ABSTRACT

This chapter examines the content of written blog postings of students enrolled in a face-to-face course focusing on literacy assessment methods and practice for Pre-Service Teachers (PST) seeking elementary teaching certification. The purpose of the study was to examine the transcription of the students' postings and Computer-Mediated Communication (CMC) to look for the three types of elements that comprise the Community of Inquiry according to Garrison, Anderson, and Archer (2001) as well as the examination of broader themes and trends across the data (Corbin & Strauss, 1990). Data included blog posts from a 15-week semester with a total of 702 combined posts and comments from a total of 40 undergraduate students. Data were analyzed using the constant-comparative method (Strauss & Corbin, 1990) and the framework of the Community of Inquiry Model (Garrison & Arbaugh, 2007). Students engaged in various levels of cognitive stages of inquiry while also building on and developing social presence throughout the course. Teacher presence also guided the social construction of knowledge throughout the course. Examination of the teacher presence suggests that the instructor needed to provide more scaffolding in modeling evidence-based practice and problem-solving on the blog as students did not always connect their practice to evidence-based or text-based support.

INTRODUCTION

An ongoing challenge for instructors is finding the best ways of using emerging technologies and tools without the benefit of robust research that what we are doing clearly benefits our students' learning and engagement. One technology tool that can be used in blended learning contexts (as well as online-only contexts) is that of the communal or shared weblog (blog) where the entire class of students can regularly post reflections, receive feedback that is visible to all, and share resources with peers. A blog is akin to an online diary and offers students a shared computer-mediated communication (CMC) space for group knowledge sharing and dialogue. In the case study described

DOI: 10.4018/978-1-4666-8246-7.ch020

in this chapter, I share how forty undergraduate students participated in a group blog in conjunction with a face-to-face undergraduate literacy course designed for pre-service teacher candidates.

The overall purpose of the qualitative exploratory study was to examine the transcription of the students' postings and computer-mediated-communication (CMC) across the semester to look for the three types of elements that comprise a "community of inquiry" according to Garrison, Anderson, and Archer (2000; 2001) as well as to examine the primary research question: *How did the communal blog function to support a "blended learning" context where learning primarily took place in a face-to-face setting?* The study examines the content of the written blogging postings of a class of students who were enrolled in a pre-service course focusing on literacy assessment methods and practice.

The undergraduate students communicated with each other within the digital blogging community and were guided by semi-structured professor-designed prompts, multi-modal supplemental readings (such as YouTube videos and podcasts) . Students were provided guidelines and a simple rubric for the blogging assignment. They posted blog commentary across the course of a full-length semester in spring, 2009. Through the blogging assignment and process, students made connections to key ideas in the course content, actively participated in an online community (within a face-to-face course), and developed their skills with digital writing and learning. The blog topics focused on their present understanding of course content as well as their goals in their case study and future teaching. The group blog served as a knowledge sharing tool towards building a community of practice (Lave & Wenger, 1991) as well as an assessment tool for participation and engagement with the course content and readings. The blog was also a way for students in a teacher education course to participate in new digital literacy practices (as described by Leu, Kinzer, Coiro, & Cammack, 2005) by reading and writing in an online-only format. This idea of group blogging in a face-to-face or blended teaching setting would be of interest to anyone teaching a face-to-face class where students share knowledge as it is being applied to specific teaching contexts or scenarios. The blogging experience would also be of broad interest to anyone looking to explore or improve their practice in the area of blended learning, broadly defined.

BACKGROUND

Community of Inquiry and Blended Learning

This research draws upon a sociocultural framework which emphasizes that learning is based on apprenticeship and teaching occurs as a result of the co-construction of knowledge in shared communities of practice (Rogoff, 1990; Vygotsky, 1962). I also draw on models of knowledge sharing and theories of tacit knowledge (e.g. Polanyi, 2009) to examine the complex ways that students supported one another in the blog space with the absence of the course instructor on the blog postings.

Within such a sociocultural framework, I specifically focus on the Community of Inquiry framework developed broadly by Garrison, Archer, and colleagues (especially Garrison & Arbaugh, 2007). In applications to online learning, this framework delineates three crucial but inter-related categories in designing and analyzing computer-mediated communication. The three types of elements that make up a Community of Inquiry according to Garrison, Anderson, and Archer (2000) include the teacher presence, cognitive presnce, and the social presence. Teacher presence is facilitated by the up-front design of the course or online experience, direct instruction by the teacher, and use of facilitating discourse (Garrison, Anderson, & Archer, 2000). Cognitive presence, for instance, includes problem-solving, application of knowledge, and attempts to solve the problem or problems; Social presence is characterized by online collaboration and expressiveness (Garrison, Anderson, & Archer, 2000).

Additionally, I draw on a broad definition of blended learning that captures the use of both online learning in conjunction with a face-to-face course setting. Blended learning can be hard to define but is generally thought of as a combination of both face-to-face teaching and online instruction to varying degrees; Picciano (2009) suggests the problem of the hard-to-define concept of "blended learning":

There is no generally accepted definition of blended learning. There are many forms of blended learning but a generally accepted taxonomy does not exist. One school's blended is another school's hybrid, or another school's mixed-mode. (p. 8).

Finally, blended learning has the potential to engage students. Garrison and Vaughan (2008) also suggest that blended learning is an active learning technique as opposed to lecture-style classes.

Distributed Cognition and Tacit Knowledge

This study is also informed by theoretical concepts from educational psychology such as distributed learning, or learning shared across groups beyond the individual's own understanding (e.g., Salomon, 1993) as well as a framework of tacit knowledge; tacit knowledge is shared through interpersonal experience (e.g., Polanyi, 2009) as well as the experience of others. Salomon (1993), in describing the types of thinking and information shared by interacting groups of people states, "People think in conjunction and partnership with others and with the help of culturally provided tools and implements." (Salomon, 1993, p. xiii)

Blogging as Blended Learning

Although there have been mixed outcomes for use of blogging with pre-service teachers as a tool for facilitating student reflection (Hungerford-Kresser, Wiggins, & Amaro, 2011; So & Brush, 2008; Top, 2011), there have been few studies on the ways that students who are novices in a practice (such as education) interact with one another to share distributed knowledge about literacy learning in a shared communal blog space. Additionally, digital knowledge sharing among students of a younger age demographic possibly has a higher level of appeal to "digital natives" who are accustomed to digital engagement in their learning (Prensky, 2001); such a practice is needed to stay current with the demographic of younger teachers within traditional teacher education programs.

METHOD

Context of the Study and Description of the Blog

The instructor of this course taught the Literacy Assessment course in spring, 2009 at a large, public university in a large urban city in the Southwest United States. The course is foundational and a required course for all teacher candidates enrolled in the elementary certification program. In conjunction with regular face-to-face settings, students also participated in required blog postings to a group course blog. The literacy course focused on furthering declarative knowledge (Snow, Griffin, & Burns, 2005), or general background knowledge related to classroom-based literacy assessment tools they will encounter in their future classroom. All students in the course were teacher candidates seeking elementary teaching certification at the university. As a required part of the course, students applied their knowledge of the course content by completing a "case study" where they assessed a child and tutored the child in areas of academic needs in reading and writing. The case study assignment began in earnest around the mid-way part of the course. At the beginning of the semester, student blog prompts designed by the instructor were based on more theoretical and conceptual understandings of the course content. However, around early March of the spring semester, students began the application component of the case study assignment and the course learning outcomes. Blog posts from March on reflected this transition towards more of an application of course content.

The instructor implemented blogging and the shared course blog as an alternative to the traditional "reflective journals" that are typically not shared in a public forum. In using interactive technologies such as blogging combined with viewing of multi-modal learning resources such as embedded videos (via YouTube) and podcasting, students engaged in a shared "community of practice" (Lave & Wenger, 1991) centered around lesson plan design and application of a case study assignment and teaching scenarios.

Data Sources

A total of 40 pre-service teacher candidates seeking initial elementary teaching certification (specifically, early childhood through 4th grade certification focus) were enrolled in the course. There were 37 females and 3 male students in the class who participated in the blog postings related to the course. The students were expected to compose and post an initial blog post as well as one to two follow-up comments on other students' initial posts. At the beginning of the course, students were required by the instructor to complete ten original posts (with follow-up replies to peers) over the course of the semester, permitting student choice in which topics they would choose to participate in. However, due to the instructor's realization mid-course that the amount of blogging may have been too much, the number of total posts required was scaled back to eight required posts over the course of the semester. The overall frequency of posts by week is listed below in Table 1 along with the weekly blog post topics. The frequency of comments includes both the student's initial post as well as any follow-up replies to peers. A total of 702 posts and comments were shared across the semester.

Table 1. List of weekly blog prompts designed to facilitate sharing and dialogue

Week	Frequency of Total Post and Comments	Topic
1	70	Welcome to [Name of Course]-Spring 2009!
2	60	Week 2: Major Concepts in Literacy Assessment
3	64	Topic for Feb. 10: Assessing Emergent Literacy
4	52	February 10: Choice Topic(s)!
5	49	Feb. 17: Choice topics again
6	49	Feb. 24: IRI's & Fluency
7	62	March 3: Word study
8	57	March 10: Resources for Case Study Success
9	51	Thoughts on ideas for case study part two-"Success stories"
10	60	March 24: Continue to share resources for your case study
11	53	Reader Response in the Classroom
12	24	April 7: Motivation
13	20	April 14: Videos on Word Study
14	13	Authentic Assessment
15	18	April 28:"Lessons Learned"

Data Analyses

Data were coded using the constant-comparative method (Straus & Corbin, 1990) and by using NVIVO 10 qualitative software. The course instructor (myself) also kept a reflexive journal during the course and used analytical memos (Miles & Huberman, 1994) while reading and rereading the blog posts for emerging themes and trends. To look at teacher presence, I examined the nature of blog post topics and the impact they had on the nature of the discussion generated by students. To examine social presence and cognitive presence, I examined the nature of the discussion that generated both socially-oriented talk as well as cognitive problem-solving discussion. My own reactions to the blogging experience and "lessons learned" were recorded in both memos and the reflexive journal (Miles & Huberman, 1994).

RESULTS

I report here the emerging themes across the blog posts as they relate to the three types of presence in the course from the Community of Inquiry Framework (Garrison, Anderson, & Archer, 2000; 2001; Garrison & Arbaugh, 2007): teacher presence, social presence, and cognitive presence. The data analyses suggest that through asynchronous discussion in a blended learning environment students engaged in various levels of cognitive stages of inquiry while also building on and developing social presence throughout the course. Teacher presence (e.g., design of the blog, guidance towards knowledge and information sharing, and resource sharing) also guided the social construction of knowledge throughout the course. Blog use by students represented both positive and productive reasons for its use as well as constraints or disadvantages.

Prominent themes arose from analyses of the data (blog posts) in looking for social and cognitive presence (Garrison & Arbaugh, 2007). Students specifically engaged in problem-solving by sharing information they found that would support another student's "plea for help". Students largely shared their specific case study scenarios and asked peers directly for ideas for helping, fostering a community of practice (Lave & Wenger, 1991). Additionally, students often drew on their own narratives and life experiences when engaging in problem-solving, for instance, by relating course concepts to their own schema or background information.

Students worked collaboratively online to design and present their lesson ideas for their case studies, even though they ultimately implemented them individually. Critical conversations that helped students to authentically reflect and evaluate their own work asynchronously through online comments and conversations fostered active learning and critical thinking. Overall, problematic areas for the course blog included students' general over-reliance on their own personal autobiographies and over-use of vignettes from their own lives; these constraints within this case study will be explored and discussed. One area of concern was that across all blog posts, few students connected their instructional decisions and thinking back to the course readings. Many of their discussions focused on connections to personal vignettes and experiences as opposed to more evidence-based practice.

Teacher Presence in the Course Blog

The teacher presence (Garrison & Arbaugh, 2007) primarily consisted of the initial course design and the creation of the blog topics and prompts. Teacher presence (e.g., design of the asynchronous discussion board and video content, guidance towards knowledge and information sharing, and resource sharing as described and defined by Garrison & Arbaugh, 2007) also guided the social construction of knowledge throughout the course. The instructor, in general, did not actively participate in the course blog and this may have hindered more in-depth cognitive problem-solving. Initially, students seemed overwhelmed with the assignment of weekly blog posting. An excerpt from a researcher memo is below and indicates this notion that there was too much instructor input in the initial blog prompts and the tasks required of students in their blog posts:

When I look back at the beginning of my first earnest attempt at designing a blog, I realize I frontloaded them with too much information. It would have been better if I had designed this so that some of this information was set up as resources. (Researcher Memo, 09/12/09)

Additionally, beyond creating the structure of the blog, I realized that I had not provided an exemplar blog posting or criteria for what constituted an effective blog post. The teacher-provided rubric for the student's blog posts was limited to the specificity of length and deadlines. An instructor memo identified this idea:

I should have provided more guidance, perhaps, in posing a scenario or question that raised the level of reflection to a more distinct cognitive goal and a shared/constructivist problem-solving scenario. However, at the beginning of a course what could a teacher assume as baseline understanding of the topic? (Researcher Memo, 09/12/09)

Overall, the teacher presence (Garrison & Arbaugh, 2007) facilitated discussion and connection of course content to the course applications, for instance, in encouraging students to share information that would help others relating to the more applied case study assignment. However, overall, as noted in the next section, students primarily focused on more "real-world" knowledge sharing as opposed to connecting their application of learning to specific course readings.

Finally, a key element of the design of the blog was that each blog prompt allowed for students to have choices as to which topics they chose to post about. The Appendix shares an example of a blog prompt that was designed by the instructor to facilitate a semi-structured online conversation by students. It was also intended to provide additional multi-media and input for students such as links to audio podcasts, links to resources on a variety of course-related topics, and more resources beyond the course readings. The intent of such multi-modality was to provide engaging yet research-based resources that would also inspire students to locate their own online resources and links to share with their peers on the blog.

Cognitive Presence in the Course: Distributed Knowledge Sharing

Five prominent sub-themes arose from analyses of the data (blog posts) in looking for cognitive presence (Garrison & Arbaugh, 2007): 1) Students applied learning and course content outside of class and reported the results of their applications on the course blog; 2) Students contextualized their understanding of course concepts to specific instances in their "real world" observations or experiences resulting in a more nuanced and complex understanding of topics 3) Students shared specific multi-modal resources such as hyperlinks and teaching resources found online; 4) Students made intertextual connections from course content to other courses, knowledge learned in class, class discussions in the face-to-face course setting, as well as their personal experiences in their blog posts and comments; and 5) Students were metacognitive (Flavell, 1976) in making sense of their understanding of course concepts, sharing thoughts, and adjusting their definitions of their emerging understanding of course content.

Applications of Learning Outside of Class

Across blog posts from the entire semester, students reported instances of trying out knowledge, or, bringing declarative knowledge into the realm of situated and applied knowledge (Snow, Griffin, & Burns, 2005). In Blog Post #7, in early March, 2009, a representative excerpt from a student's post shows a more nuanced understanding of the text reading and how it applied to their tutoring of a student:

In my volunteer work I actually had the opportunity to do what Ch.6 McKenna and Stahl is [sic] talking about….Anyways I am tutoring a first grader who is struggling with reading. In our last session I had her read over a list of 100 high frequency words.

In this way, students progressed, generally, from more textbook-centered posts in the very beginning to more complex posts where knowledge was applied, towards writing with a contextualized setting and application in mind. Students even applied the learning about strategic reading instruction to their own learning in higher education settings and reported this on the blog. Another student shared such a personalized application:

Another thing that I found interesting in this chapter; was the summary writing. Barbara Taylor's five-steps in writing coherent hierarchical summaries are most helpful….I'm applying this to my own reading comprehension strategies for my ____ class [another course]. The text is overwhelming and I think this will help me to be more successful with breaking the material down and getting the main idea. (Blog Post #7)

Overall, students were able to connect their learning to specific applications and contexts beyond the textbook readings.

Resource Sharing

Students specifically engaged in problem solving by sharing information they found that would support another student's "plea for help". Students, for instance, shared their specific case study scenarios and asked their peers directly for ideas for facilitating success in their case study assignment (tutoring a child one-on-one) for specific curricular ideas and materials, again, fostering a community of practice (Lave & Wenger, 1991). Some sub-themes of this type of problem-solving are listed below:

- Student sharing of hyperlinks (URL's) with a brief description of what resource could be found at the website. Students often provided an evaluation of what they located and how beneficial they felt it was to their application towards the case study assignment and their related tutoring experience.
- Intentional sharing of resources from other courses. Students referenced resources from another literacy course.
- Sharing and reporting of knowledge gleaned from field observations related to another course. For instance, a student shared what she was seeing in a field observation as well the link where others students could seek further information: "My mentor teacher told me that they use a Developmental Reading Assessment to determine students reading level. Each small group is done by the level of the students and she gets her books for students from: http://www.readinga-z.com" (Blog Post #3)

Interestingly, students began sharing more links to outside resources that pertained to literacy assessment and literacy teaching in early March, when the case study assignment began and the course shifted more from a "textbook" focus to more of an application focus. Overall, by sharing their resources and suggestions, students were able to provide teaching ideas collaboratively amongst themselves; some students mentioned that they would be following other's advice, thus, expanding the amount of resources that could be learned beyond the textbooks and course lecture. One student shared, "You have a great list there about some of the activities that we can use for our students in our classrooms. I know I will be utilizing most if not all of them." (Blog Post #6).

A related theme to resource-sharing was "information-seeking". For example, students posed questions to their peers where they sought out further information and looked to classmates on the blog for some type of advice, resources, or general ideas as they engaged in the practice of tutoring and assessing a student. This was especially apparent from Blog Post #7 and #8 forward to the end of the semester. Similarly, students also engaged in "advice giving" where they provided direct advice (both solicited and unsolicited) or "cautionary tales" to classmates. One student shared:

I thought that it would not really matter if I spent a lot of time organizing. WRONG! I learned from experience that taking that extra 10 or 15 minutes to get organized and plan out what I want to do in the session actually saves time in the long run. (Blog Post #10)

Contextualized Understanding to High-Interest "Real World" Topics

Students found certain course topics problematic, such as the topic of how standardized testing differed from the notion of informal assessment in the classroom. Students engaged in a nuanced online conversation about this "real world" topic in the communal blog space while also debating the complexities of the advantages and disadvantages of standardized testing. The online blog conversation was one where diverse viewpoints were shared. Another topic that generated interested in the blog and stimulated a lot of online discussion was the topic of "round-robin reading". This is a traditional teaching practice where elementary or secondary students read aloud one at a time. Students generated much dialogue in Blog Post #7 about their own experiences with round-robin reading in school and what they thought were better alternatives to this teaching practice. Discussions on both of these topics on the blog were extensions of conversations begun in the face-to-face setting. A representative quote about the round robin reading topic from Blog Post #7 follows: "I wanted to focus on our discussion last night of round-robin reading. I really enjoyed that topic because I felt like I learned a lot about why not to use the technique and alternatives to use in my classroom." (Blog Post #7)

Intertextual Connections

In their blogs posts and comments, most students made intertextual connections (as defined by Lemke, 1992) from the course to other courses, some course readings, and readings from other courses, as well as connections made to their field placements and case study. Intertextual connections can be thought of as the following, as described by Jay Lemke, "Every text, the discourse of every occasion, makes its social meanings against the background of other texts, and the discourses of other occasions." (1992, p. 257) There were several types of intertextual connections made across blog posts. Because many of the semi-structured prompts provided by the instructor (see Appendix for a representative example) encouraged or required students to draw on the textbook readings and/or the multi-media content provided in the blog prompt, nearly all students made connections to the said textbook and/or multi-media content, as required. In addition to providing their commentary on the textbook readings, students made the following intertextual connections in their posts and comments: 1) connections from course content to personal narratives or personal schema as a way to understand concepts; 2) connections to knowledge from other courses they were concurrently taking or had previously taken and 3) connections to experiences such as observations from a field experience placement where they had the chance to observe some of the ideas relating to the course topic of literacy assessment as it applied to teaching practice.

As students participated in their field observations, they shared this knowledge and wove it into their posts. In this way, they provided sense-making for their own understanding and connection to practice, but also provided insight for students who were not in that particular setting. Some examples of intertextual connections follow:

- "I have learned from last semester to find ways to keep the childrens' attention and try to make it fun." (Blog Post #1)
- "Today, as well as last week, I observed in a kindergarten classroom. It was really neat to see some of the things we have been talking about being implemented in the classrooms." (Blog Post #4)

Additionally, some intertextual posts contained multiple instances of connections made. For example, in the following quote, the student makes connections to a course from a previous semester as well as to a connection related to learning from the face-to-face setting from the course. This indicated the student was drawing on multiple sources of prior knowledge when making sense of course material:

After learning about literacy assessment last semester and discussing it in our first class I have come to realize that there are many other ways to assess and child to make sure they know how to read and write and that they actually understand the material. (Blog Post #1)

Overall, students made complex connections across blog posts and drew upon multiple sources of information, including the face-to-face settings when composing blog posts and commentary.

Metacognitive Posts: "Thinking Aloud" about Emerging Understanding

Throughout the posts, and especially at the beginning of the blogging experience, many students wrote about their emerging understanding of course content. Because the course content was largely new to many students and the class size was fairly large in the face-to-face course, the main advantage of the blog—besides resources sharing—was the chance to provide a forum where all students could participate in sharing their thoughts, beliefs and responses to the readings.

First, across the blog posts students were metacognitive, or aware of their own thinking and their sense-making (as defined by Flavell, 1976) as they attempted to make sense of concepts and what was beginning to make sense to them. Students noted when they were having difficulty understanding course content and stated this explicitly in their blog posts. They expressed when they had a limited understanding of a topic and had more to learn about a topic. They engaged in self-monitoring and self-assessment as they read the course materials. Some students posed questions about areas in which they sought further understanding. They also shared changing definitions that were transformed as they made progress in the course and especially as they made connections to their experiences in real classrooms and in their work for the case study assignment for this course where they tutored an individual student in the area of literacy instruction. In writing research memos (Miles & Huberman, 1994), I noted that by reading through student posts on the blog, I was able to use students' written blog comments and students' self-reported understanding as formative data of what course topics in the textbooks engaged them and which topics they may have found confusing. Examples of sense-making and metacognitive postings by students follow:

- "Phonemic awareness has always been a little confusing for me up until now. The book gives great examples of how to assess students." (Blog Post #3)
- "Everything we are learning in class is really starting to come together with seeing in it videos and reading about how other people have experienced it in the classrooms they are observing."(Blog Post #5)

In conclusion, regarding the cognitive presence (Garrison, Anderson, & Archer, 2001; Garrison & Arbaugh, 2007), overall, there was a variety of type of posts and comments ranging from more analytical to more emotional and affective posts and comments such as the overly personal responses and purely unsubstantiated opinion. However, overall, most students connected what they said to some type of background knowledge either grounded in experience(s), other knowledge sources, or specific texts. An emerging ability to connect theory (course content and topics) to practice was present in many of the blog posts. This provided an initial footing for students on which to connect face-to-face class discussion to the blog posts as well as extend on topics that were more nuanced and complex in scope, for instance, in the discussion and viewpoints expressed relating to the topic of standardized testing. By connecting their course topics to multi-faceted experiences and knowledge students were able to discuss topics well beyond the scope and limitations of the face-to-face setting.

Social Presence in the Course Blog

In this section, I describe the social presence that permeated some of the student blog posts. As defined by Garrison & Arbaugh (2007), the social presence is a crucial component of the computer-mediated communication. It serves to facilitate communication when engaging in the cognitive presence or problem-solving scenarios in online settings; according to Garrison & Arbaugh (2007), social presence includes the ability for students to take risks in sharing and express themselves in social capacities. The social presence as seen in the student blog posts and comments included the following key themes: 1) Students expressed appreciation and thanks for the idea sharing with each other, building a community of practice (Lave & Wenger, 1991) and a Community of Inquiry (Garrison & Arbaugh, 2007); 2) Students recognized and empathized with one another when they weren't fully understanding course ideas and had anxieties related to future teaching and understanding of course content; and 3) Students were envisioning towards their future teaching and projecting an identity of their professional self into the shared discourse about teaching and assessing that took place in the blog setting.

First, students expressed direct statements of gratitude and thanks towards their peers for sharing information, enhancing their understanding of course content and concepts, and sharing of anecdotes/narratives that related to experiences and observations of teaching-related scenarios. The following are statements that expressed this sentiment:

- "I have the same questions and concerns as you do." (Blog Post #1)
- "Thank you for the insight!" (Blog Post #1)
- "I think it's so neat that we have such a strong bond between all of us Education majors- keep posting hands-on experiences, [sic] this is great stuff! (Blog Post #3).
- "It's amazing to hear all of the different activities that can be implemented for alphabetical and phonological development. I was thinking too that you could even implement that into the other curriculum." (Blog Post #4)
- "It is comforting to know that someone else agrees with me regarding the negative aspects of Round Robin Reading." (Blog Post #7)
- "Thank you for mentioning Barbara Taylor's five steps to writing summaries for hierarchical summaries. I need to practice on doing this for our [name of another course] class also." (Blog Post #7)

Students were inspired to try out other's ideas in their case study assignment. One student shared on a blog post early in the course:

I want to be able to do what you did with the boy in your tutoring session. I want to be able to see the difference between if they are reading for meaning or for testing. This is something I cannot wait to see and try for myself. I want to encourage you to keep it up and focus because it sounds like you will be awesome at what you are doing! Thanks for sharing. (Blog Post #4).

Another student, later in the semester, also expressed that she was inspired to try out a peers' idea and was grateful to have had the shared resource:

The website you gave, http://bookwizard.scholastic.com is GREAT! I really needed some help with books that are on a certain grade level. The website can be specific or broad and it gave me 5 pages of books. I am really excited to go to the library and check some of these out to try with my first grader in my case study. Keep the websites coming! I write them down for future reference and I think many of them are very helpful. (Blog Post #8)

Second, students, especially at the beginning of the course and in their first few blog posts, expressed anxiety about understanding course concepts, about being able to properly assess students in their future classroom, and other concerns about teaching in general.

Third, most students, as novices in the field of teaching, were in the process of forming their identities as future teachers. They expressed this anticipation of having their future classrooms across many of the blog posts. Some of their posts were contextualized by a framing of their learning as it applied to them as future teachers. Examples include the following:

- "In the future classroom I will have a variety of text available because each child may be at a different level and may enjoy a variety of different books." (Blog Post #2).
- "Even so, I am beginning to feel a lot better about going into the classroom to teach, especially after observing real teaching in action." (Blog Post #5)

Essentially, students provided a great deal of peer-to-peer support regarding course topics, and, later in the semester, support to each other as both university students and as future teachers.

DISCUSSION

In using asynchronous (not taking place in real time) technologies such as blogging combined with viewing of embedded videos (via YouTube) and podcasting, students engaged in a shared "community of practice" (Lave & Wenger, 1991) centered around lesson plan design, literacy assessment topics, and teaching practices and scenarios. This community and knowledge construction was not otherwise possible when only teaching and learning in face-to-face classrooms on a university campus. The communal course blog in this literacy assessment course in a teacher education program at a large university served as a place to encourage students to pose questions to each other and to compare their prior knowledge with their ongoing and possibly emerging understandings about the complex topic of classroom literacy assessment.

This Community of Inquiry framework (Garrison & Arbaugh, 2007) seemed especially useful for noting teacher presence and social presence. The cognitive presence was trickier to examine and analyze as it was often interwoven with the social presence. The subject of this literacy assessment course posed new information and content to students, many of who had little to no experience in working with children in an applied setting as required by the nature of the class. Many of their initial posts reflected this anxiety of being responsible in the near future for a roomful of children and having to know and practice the what, why, when, and how of literacy assessment. As such, pre-service teachers benefited from a support system that offered not only declarative knowledge about literacy instruction (Snow, Griffin, & Burns, 2005) but also the social and affective components of being supportive to one another through an online social presence (as described by Garrison& Arbaugh, 2007). This communal course blog served in these capacities of social and cognitive presence; however, the cognitive presence was more limited in that students drew more on their experiences and personal narratives in seeking out resources and advice to their fellow students.

The teacher presence needed to be developed much more strongly in order to better intentionally model using research-based and evidence-based approaches towards teaching practices. Implications include further seeking ways to help scaffold these evidence-based approaches in an online forum. For instance, the instructor can provide and demonstrate concrete ways for students to "lend" this support to each other by designing specific prompts students can use to be helpful while also connecting to research and evidence-based practice. One idea might be, frontloading the students with examples and direct instruction of what it means to connect literacy assessment to research and evidence-based practice. Studnets could also self-asses their own blog posts according to a rubric that required them to connect their thinking to course readings, research, and descriptions of evidence-based practice. Because students were making intertextual connections in their blog posts, instructors in cohort-based programs should intentionally learn about the other instructors' courses who teach related content in order to foster such intertextual connections across courses and subject areas.

Academic and research implications of this study include continuing to focus on seeking ways to use asynchronous learning tools such as blogging to foster reflective thinking and knowledge sharing in both face-to-face and online courses. Research can seek students' input and feedback on the blogging experience through additional measures such as surveys and focus group interviews. The limitations of this study include the idea that data was collected only from the blog postings themselves. The instructor will continue to reflect on the ways that the Community of Inquiry Framework (Garrison & Arbaugh, 2007) provides an intentional and purposeful way to design and facilitate computer-mediated-communication to support learning in blended learning contexts.

KEY TERMS AND DEFINITIONS

Asynchronous Learning: The type of learning that occurs in online settings whereby learners do not have to respond in real-time; learning can take place at the learner's own pace within structured parameters, for instance, deadlines and prompted online discussion.

Blended Learning: A learning context where students may participate in both on-campus (face-to-face) learning settings as well as online learning settings.

Blog: An abbreviated term to describe a weblog or an online journal that is written in reverse chronological order and allows for interactive online discussion through posting of comments.

Cognitive Presence: A focus of an online learning experience where students are engaged in problem solving and other cognitive tasks.

Communal Blog: An online weblog where participants are all posting and commenting to one centralized blog rather than their own individual blogs.

Community of Inquiry: An online learning community where learners engage socially while exploring the cognitive dimension of inquiry, for instance, by problem-solving together in an online forum.

Community of Practice: A reflective and supportive learning community where learners are working towards shared learning goals; this often involves more experienced learners assisting more novice learners in their practice.

Intertextuality: Knowledge that makes explicit connections across texts including diverse mediums such as textbooks, audio files, references to other learning contexts, and other sources of information.

Social Presence: A focus of an online learning experience that intentionally fosters social support such as building community and interpersonal interactions beyond academic learning tasks.

Teacher Presence: The intentional design of an online learning experience that fosters cognitive development of students while creating a community of supported learning.

Week 2: Major Concepts in Literacy Assessment

with 60 comments
The class agenda for Week 2 is here: Week 2 Agenda.
The PowerPoint for Week 2 is here: Major Concepts of Literacy Assessment PPT.

*****Please print and read the Rubric for Blogging and Service Reflections. I will go over in class.*** Click here: Rubric.

This is the blog post for Week 2. You can start posting now. The post for week one is prior to this one. Post your initial post by 11:59 p.m. on *Monday, February 2*. Comment on at least one other post by 11:59 p.m. on Wednesday, January 28. Topic 2 will be closed for posts and comments at *11:59 p.m. on Wednesday, February 3*. Please be sure your initial post is 2-3 solid paragraphs; your writing should be reflective and thoughtful, not shallow or superficial, and show a connection to the readings.

This link (click) goes to a searchable database where you can see just about every common assessment available for reading assessment. Most schools primarily use TPRI, DRA, and Flynt Cooter reading inventory to assess reading. Here is also an (optional) intriguing link about what assessments are mandatory in our surrounding states, including Texas.
The post topic is the following:

What are the major tools and domains of literacy assessment and how do you envision using them in your future classroom? How can literacy be used to inform instruction? That is, how will the day-to-day formative (ongoing) assessments you will do in the classroom help you to actually plan meaningful instruction and lesson plans that will maximize literacy learning and achievement for your students? (This question is the "big question" of the entire course!).

You can also respond or connect to both the readings and/or the links and podcast (highly relevant on his concerns for "over-testing") below.

Optional Links:
Texas Primary Reading Inventory (given to K-2 children in Texas several times a year to screen for dyslexia)
Released TAKS tests
NAEP Reading Test (national)
Podcast by Dr. Peter Afflerbach on reading assessment.

This link goes to a really great site on emergent literacy assessment, one of our course topics. It has short videos on it, as well of each type of assessment: Early assessment tools._

Chapter 21
Implications of Mobile Devices in a Bachelor of Education Program

Norman Vaughan
Mount Royal University, Canada

Kimberley Lawrence
University of Calgary, Canada

ABSTRACT

The purpose of this chapter is to describe a study that investigated if and how mobile devices could be used to support the required program outcomes in a blended Bachelor or Education (B.Ed.) program. All students enrolled in an educational technology course during the Fall 2011 semester were provided with a ViewSonic Tablet. Through faculty interviews, student online surveys, and a post-course focus group, the study participants indicated that mobile devices could be useful for supporting future professional responsibilities (e.g., career-long learning, collaboration) and facilitating student learning but less effective for planning, assessment, and managing the classroom environment.

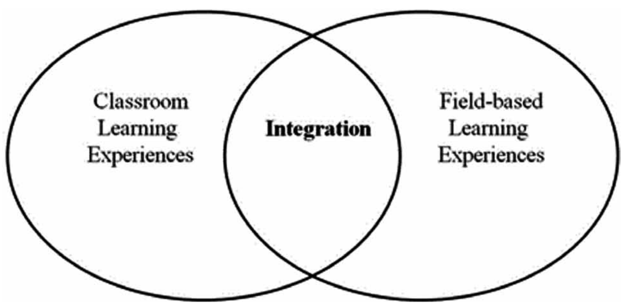
INTRODUCTION

The idea of blending different learning experiences has been in existence ever since humans started thinking about teaching (Williams, 2003). What has recently brought this term into the limelight is the infusion of web-based technologies into the learning and teaching process (Allen & Seaman, 2010; Clark, 2003). These technologies have created new opportunities for students to interact with their peers, teachers, and content.

Blended learning is often defined as the combination of face-to-face and online learning (Sharpe et al., 2006; Williams, 2002). Ron Bleed, the former Vice Chancellor of Information Technologies at Maricopa College, argues that this is not a sufficient definition for blended learning as it simply implies "bolting" technology onto a traditional course, using technology as an add-on to teach a difficult concept or adding supplemental information. He suggests that instead, blended learning should be viewed as an opportunity

DOI: 10.4018/978-1-4666-8246-7.ch021

Figure 1. Bachelor of education approach to blended learning



to redesign the way that courses are developed, scheduled, and delivered through a combination of physical and virtual instruction, "bricks and clicks" (Bleed, 2001). The goal of this redesigned approach to education should be to join the best features of in-class teaching with the best features of online learning to promote active, self-directed learning opportunities for students with added flexibility (Garnham & Kaleta, 2002; Littlejohn & Pegler, 2007; Norberg, Dziuban, Moskol, 2011). This sentiment is echoed by Garrison and Vaughan (2008) who state that "blended learning is the organic integration of thoughtfully selected and complementary face-to-face and online approaches and technologies" (p.148).

Most of the recent definitions for blended courses indicate that this approach to learning offers potential for improving the manner in which we deal with content, social interaction, reflection, higher order thinking and problem solving, collaborative learning, and more authentic assessment in higher education (Graham, 2006; Mayadas & Picciano, 2007; Norberg, Dziuban, Moskal, 2011). Dziuban and Moskal (2013) further suggest that "blended learning has become an evolving, responsive, and dynamic process that in many respects is organic, defying all attempts at universal definition" (p.16). For the purpose of this research study, blended learning is defined as the intentional integration of classroom and field-based learning experiences through the use of digital technologies such as mobile devices (Figure 1).

There have been a variety of definitions used for the concept of mobile learning. It has been suggested by Brasher and Taylor (2005) that mobile learning is "any sort of learning that happens when a learner is not at a fixed, predetermined location, or learning that happens when the learner takes advantage of the learning opportunity offered by mobile technologies" (p.33). The Mobile Learning Network (2013) in the United Kingdom states that mobile learning is ". . . the exploitation of ubiquitous handheld technologies, together with wireless and mobile phone networks, to facilitate, support, enhance and extend the reach of teaching and learning" (What is Mobile Learning? section, para 1). Ally (2009) indicates that *M-learning* focuses on the delivery of electronic learning materials, with built-in learning strategies, on mobile computing devices to allow access from anywhere and at anytimehttp://www.google.com/url?q=http%3A%2F%2Fnet.educause.edu%2Fir%2Flibrary%2Fpdf%2FELI3022.pdf&sa=D&sntz=1&usg=AFQjCNG8M8FIkAgR_Xu4g-z8sk8lIekweRQ while *E-learning* involves the delivery of electronic learning materials on desktop and notebook computers. And, the EDUCAUSE Learning Initiative (Brown & Diaz. 2010) attempts to create classifications for mobile learning based on the size of the device. For example, *highly mobile devices* are cell-phone sized devices that can fit in a pocket: feature phones (supporting cell and SMS service only), smartphones, and other devices like Flip cameras. *Very mobile devices* are slates, pads, and netbooks. *Mobile devices* are larger devices such as laptops. This classification system was utilized in this study in order to differentiate the affordances that different sizes and types of mobile devices have on supporting the required program outcomes in a blended pre-service teacher education degree.

There have been previous research studies about the use of mobile devices in higher education (Gikas & Grant, 2013; West, 2012; Zhu et al., 2012). These studies have primarily investigated the advantages and disadvantages of using these

Table 1. Bachelor of education field-based learning experiences

Year Four	9 week practicum combined with 4 program of studies courses and a capstone experience course

devices in university courses whereas this study focused on how mobile computing technologies could be used to support program learning outcomes in a Bachelor of Education program (B.Ed.).

STUDY CONTEXT

The blended pre-service teacher education program described in this study takes place at Mount Royal University, a four year undergraduate institution located in Calgary, Alberta, Canada (http://www.mtroyal.ca/). A new Bachelor of Education (B.Ed.) program was launched in the fall of 2011 (http://www.mtroyal.ca/bed/). This is a four year direct entry B.Ed. degree. The emphasis of this program is on connecting theory with practice through early, consistent, and on-going field experiences. In the first, two years of the program students have a core education course each semester that meets once a week and is linked to a twenty or thirty hour field-placement. In the third and fourth years of the program, the students have extended field placements that are connected to program of studies courses and a capstone experience that are designed to integrate theory (of the coursework) and practice (of the field experiences) (Table 1).

The purpose of this research study was to investigate if and how mobile devices could be used to support the required program outcomes in this blended pre-service teacher education degree. All students enrolled in an educational technology course during the fall 2011 semester were provided with a *ViewSonic* Tablet. Faculty interviews, student online surveys, and a post-course focus group were conducted as part of this investigation. The following two questions were used to guide this study:

1. What kind of mobile devices do students and faculty currently own and what kind of applications do they use on these devices?
2. How do students and faculty perceive that these devices can be used to support the required program outcomes in a blended pre-service teacher education degree?

Theoretical Framework

The literature on community of practice and social learning theory informed the methodology and methods of this study. The perspective of learning as increasing participation in communities of practice is embedded in a relational and situated understanding of knowledge (Lave & Wenger, 1991). This social theory of learning defines communities of practice as "a set of relations among persons, activity, and world, over time and in relation with other tangential and overlapping communities of practice" (p. 98).

Wenger (1998) links the formation of a community of practice with three participatory dimensions: engagement, accountability, and negotiation. Engagement is dependent on developing an understanding of how to interact with other people within the community such as students and faculty in pre-service teacher education program. Becoming accountable to an enterprise, for example a set of program outcomes, prompts members to consider certain possibilities that contribute to aligned perspectives of the world. Wenger refers to negotiation as the ability to interpret and make use of a repertoire of the community's practice. In the context of this study, this involved practice, discussion, and reflection on how mobile devices could be used to support the program outcomes for a B.Ed. degree.

Recognizing the connection between learning and the formation of a community of practice, an action research methodology was utilized.

Methods of Investigation

An action research (Stringer, 2007) and case-based method (Creswell, 2013) were adopted to investigate how digital technologies could support student assessment in higher education. There are various forms of action research and the framework defined by Gilmore, Krantz and Ramirez (1986) was utilized:

Action research . . . aims to contribute both to the practical concerns of people in an immediate problematic situation and to further the goals of social science simultaneously. Thus, there is a dual commitment in action research to study a system and concurrently to collaborate with members of the system in changing it in what is together regarded as a desirable direction. Accomplishing this twin goal requires the active collaboration of researcher and client, and thus it stresses the importance of co-learning as a primary aspect of the research process. (p.161)

In addition, Stringer (2007) indicates that action research is a reflective process of progressive problem solving led by individuals working with others in teams or as a part of a "community of practice" to improve the way they address issues and solve problems. This research approach should result in some practical outcome related to the lives or work of the participants, which in this case is the effective use of mobile devices in future K to 12 teaching practice. http://www.web.net/~robrien/papers/arfinal.html - _edn1

There have been concerns about the validity of this methodology as it is often carried about by individuals who are interested parties in the research (i.e., faculty members) and thus, potentially biased in the data gathering and analysis (Pine, 2009). The justification for action research counters this criticism by suggesting that it is impossible to access practice without involving the practitioner. Practice is action informed by values and aims, which are not fully accessible from the outside. The practitioner may not even be wholly aware of the meaning of his or her values until she or he tries to embody them in her action (Kemmis, 2009).

This approach consisted of a mixture of quantitative (i.e., survey) and qualitative (i.e., interviews and focus group) research methods.

Data Collection

The principal researcher for this study was also the educational technology course instructor and thus, data was collected by an undergraduate student research assistant (USRA) in order to minimize perceptions of coercion and bias. The USRA invited all students enrolled in the course to be part of this research project and a total of 14 students participated in this study (100% response rate). In addition, she invited all of the faculty members in the pre-service teacher education program to participate in a 30 minute interview on the topic of mobile learning (n=6). The project received institutional ethics approval and the students and faculty members signed an informed consent form. The consent form offered the participants confidentiality and the ability to withdraw from the study at any time.

The data collection process began with a pre-course online survey that was designed by the principal researcher and has not been validated statistically (Appendix A). The purpose of this survey was to collect base-line data about what kind of mobile devices students currently owned and what kind of applications they used on their devices. As well as determining students' initial perceptions about how these devices (tablets in particular) could be used to support the required program outcomes of the pre-service teacher education degree. The survey consisted of a mixture of Likert-scale and open-ended questions and the second version of the online *Free Assessment Survey Tool* (http://toofast.ca) was utilized.

The faculty interviews were also conducted at the beginning of the fall 2011 semester and the questions were identical to those used for the student pre-course online survey (Appendix B). These 30 minute face-to-face interviews took place in each of the faculty members' offices. Each of these interviews was facilitated, recorded, and transcribed by the USRA.

Throughout the semester the student participants engaged in a series of learning activities that required the use of their *ViewSonic Tablet*. For example, the students used their tablets to create a lesson plan, video record a group teaching demo, provide audio assessment feedback to one of their peers, and develop an online tutorial about an *Apple* or *Android App* for educational purposes. After each learning activity, the students were encouraged to post their reflections to a research wiki on mobile devices (http://tinyurl.com/mobileresearchwiki).

At the end of the semester, the students were asked to complete a post-course online survey about their perceptions of how mobile devices could support the required program outcomes in the pre-service teacher education degree as well as their recommendations and strategies for effectively using mobile devices in the program. The students were also invited to participate in a 30 minute post-course focus group with the USRA to discuss the online survey and research wiki findings. Eight students volunteered for this focus group and the session was digitally recorded and transcribed by the USRA.

Data Analysis

A constant comparative approach was used to identify patterns, themes, and categories of analysis that "emerge out of the data rather than being imposed on them prior to data collection and analysis" (Patton, 1990, p. 390). The pre- and post-course student online survey results were exported into *MS Excel* for descriptive statistical and thematic analysis by the USRA and the course instructor. The faculty interviews were transcribed in *MS Word* by the USRA. The survey data was correlated with the faculty interview responses throughout the semester. At the end of the semester, a preliminary report was compiled and emailed to each of the student participants who were then invited to participate in a post-course focus group to discuss the initial study findings. The transcript from this focus group was reviewed and compared with the student survey and faculty interview data in order to triangulate the themes and patterns.

FINDINGS

This section begins with a demographic profile of the student participants followed by a summary of the results for each of the two research questions:

1. What kind of mobile devices do students and faculty currently own and what kind of applications do they use on these devices?
2. How do students and faculty perceive that these devices can be used to support the required program outcomes in a blended pre-service teacher education degree?

Demographic Profile of Student Participants

In order to establish a context for the study findings, the pre-course survey asked a series of demographic questions. The demographic profile of the students is summarized in Table 2.

Table 2. Survey respondent demographics

Item	Percentage/ Number
Off-campus accommodation within driving distance (57% lived with their parents)	100%
24 years of age or less	100%
Employed (part-time 79%; full-time 0%)	79%
Female	86%
Second year of studies	94%
Average number of courses enrolled in/ semester	4

The majority of respondents were second-year students who were employed on a part-time basis, commuted to campus, and lived at home with their parents. Respondents were all under the age of twenty-five and approximately 86% percent were female. The demographic profile of student participants reflects that of the university as a whole with respect to age, employment status, residence, and level of course enrollment with the exception of gender (Prairie Research Associates, 2011). Approximately two-thirds of the Mount Royal University student population is female and the higher percentage of females in this study is due to a higher concentration of female students in our Bachelor of Education program.

Student and Faculty Ownership and Use of Mobile Devices

At the beginning of the fall 2011 semester, students and faculty were asked to identify what types of mobile devices they owned and what kind of applications they used on these devices. The results are highlighted in Figures 2 and 3.

In terms of mobile device ownership, all of the students and faculty who participated in this study had laptops, 92% of the students had SMART phones compared to only 33% of the faculty, and only 1 student (7%) and 2 faculty members (33%) had their own tablets. The students primarily used their mobile devices for communication and social networking while the faculty members used these devices for academic purposes and navigation. The students also used their SMART phones to capture and share digital images and videos while the faculty were not familiar with how to perform these operations. The differences in student and faculty ownership and use of mobile devices is similar to the results of a study conducted at the University of Texas, Brownsville where 94% of the students reported that they were ready for mobile learning compared to only 60% of the faculty members (Corbeil & Valdes-Corbeil, 2007).

Ability of Mobile Devices to Support Required Program Outcomes of a Pre-Service Teacher Education Program

Recently, Alberta Education has created a draft of professional practice competencies for K to 12 teachers (Government of Alberta, 2011). These competencies consist of the following five categories:

1. Planning and preparation.
2. Assessment.
3. Facilitation.
4. Classroom environment.
5. Professional responsibilities.

Students were asked in the pre- and post-study online surveys to rank and comment on how mobile devices (specifically tablets) could be used to help them achieve each of these five program outcomes. Faculty members were asked similar questions in their face-to-face interviews with the USRA. Both groups ranked professional responsibilities as the number one competency that could be supported through the use of mobile devices (Table 3). Students indicated in the post-course focus group that human contact was more important than computer-mediated communication when learning and practicing professional responsibilities such as ethical behavior. This is reflected in the post-

Figure 2. Student and faculty ownership of mobile devices

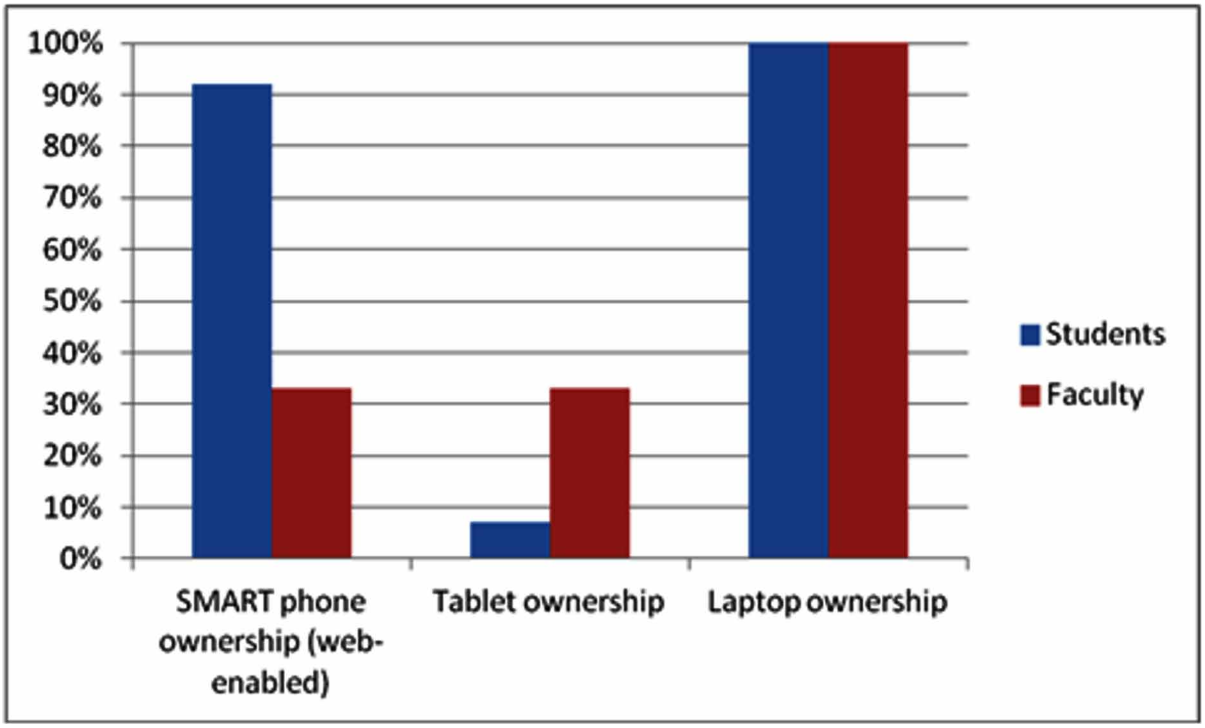

Figure 3. Student and faculty use of mobile devices

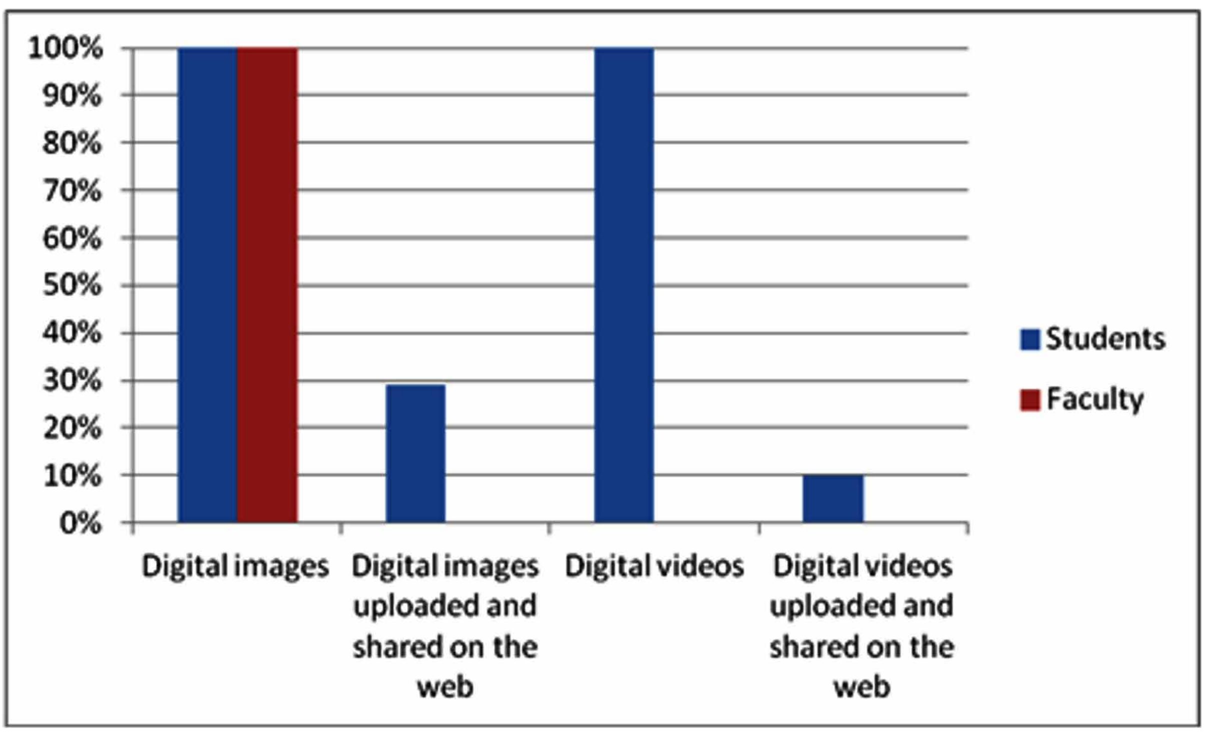

Table 3. Professional responsibilities

	Faculty	**Student Pre-Study**	**Student Post-Study**
Valuable/ Very Valuable	83%	93%	64%
Related Comments	*Tools of the trade—important to know "first hand" the pros and cons of using mobile devices in K to 12 education.*	*It keeps you updated on the current and emerging technology. As a future K to 12 teacher this is very important not only to keep you up to date but to keep your class engaged by using technology that relates to their generation.*	*While using the tablet, I found that I had full access to the internet. The internet is the key when finding information and workshops to attend.*

Table 4. Facilitating student learning

	Faculty	**Student Pre-Study**	**Student Post-Study**
Valuable/ Very Valuable	83%	86%	72%
Related Comments	*Facilitating student learning in different ways - making videos to help students (ex: philosophy, a math probe)*	*Every student has a unique way of learning and by varying the method one uses to teach, teachers can meet the needs of more students. Mobile devices give us so many different ways to facilitate student learning. There are computer games designed for students to work hands on with all different types of curriculum. They also allow students access to more sources then just their teacher.*	*Tablets have given me the opportunity to include technology in a more authentic way.* *I think we are in an age that has put an increasing emphasis on hand-held technology and it's only a matter of time before children are learning and completing homework on them.*

study survey results where only two-thirds of the students indicated that mobile devices were valuable for developing professional responsibilities.

The second highest ranked competency was facilitating student learning. Both faculty and students commented that mobile devices could be used to facilitate different authentic learning pathways for K to 12 students (Table 4). Again, the students in the post-course focus group emphasized the importance of human contact when facilitating learning and thus, the decrease in the percentage of students in the post-study survey who indicated that mobile devices are valuable for this program outcome.

Initially, students and faculty were moderately positive about the ability of mobile devices to support the planning and preparation process for learning but in the post-study survey students commented on the technical restrictions and challenges of using tablets and SMART phones to create lesson plans (Table 5).

In terms of the ability of mobile devices to be used to assess student learning, the faculty members were much more optimistic than the students. In both the pre- and the post-study surveys, students expressed concern about the emphasis on digital feedback preferring a balance with oral and hand-written forms of assessment communication (Table 6).

Finally, both faculty and students expressed concern about the impact of mobile devices on the classroom environment. Both groups commented that these types of devices could become very distracting if not properly integrated into the learning process (Table 7).

Table 5. Planning and preparing for learning

	Faculty	Student Pre-Study	Student Post-Study
Valuable/ Very Valuable	67%	64%	29%
Related Comments	*Program of Studies Guides and Resources are all web-based – just a click away Caution: just because it's on the web doesn't mean it's valuable. Need to look at and know it is well researched.*	*Mobile devices are essentially computers. They allow teachers to lesson plan anywhere in the world. Teachers can do research or search for information at any time during the day.*	*I prefer to lesson plan on a laptop, computer or netbook because I have access to a full keyboard. The tablet is helpful when needing to look over a plan that you may have forgotten at home.* *I don't feel like these devices are efficient enough to use for lesson planning...the wi-fi is difficult to connect to at times, and it's tricky to type on. I'd much prefer to do a lesson plan on a computer.* *I'm not sure that they would be ideal for 'Planning for Learning' because of the small keyboard and screen. I could see it becoming annoying.*

DISCUSSION AND RECOMMENDATIONS

The students in the post-study survey and focus group were asked to provide a series of recommendations and strategies for using mobile devices effectively in a blended pre-service teacher education program. They have been grouped into the following five categories (Table 8).

The students indicated that educational design and personal choice were key elements to the successful use of mobile devices in a blended pre-service teacher education program. They emphasized that without a specific rationale for using these devices to support the intended learning outcomes of a course assignment or field-based learning experience these digital tools could quickly become an expensive and frustrating distraction. They also recommended that institutional IT infrastructure needs to be in place in order to ensure the efficient use of mobile devices and this includes proper mobile apps, devices, and wireless internet connectivity in classrooms and laboratories.

Table 6. Assessing student learning

	Faculty	Student Pre-Study	Student Post-Study
Valuable/ Very Valuable	83%	50%	23%
Related Comments	*These devices can be used to give richer feedback- e.g., video tape the student teachers doing the teaching. And then sit down and discuss video or can review their research paper and provide audio rather than text-based feedback.* *Focus on process rather than just product. Have a video of a group working on things. Used to tape grade ones reading and let them listen to it to see what they needed to work on. Self-assessment. Watch video of self (presentation)*	*This will come in handy if instead of written comments, students can see their teacher or peers evaluating them through video for example.* *This could be a great way of inputting current grades into electronic form, especially if you are out of town (not near a computer) or if you're home computer decides to crash on you.*	*I find that hand written feedback is better when marking because it doesn't make my eyes feel as tired. I also prefer to give oral feedback. No doubt hand-held devices have a place in innovative learning, but marking homework/assignments is probably not where you'll see it.*

Table 7. Classroom environment

	Faculty	Student Pre-Study	Student Post-Study
Valuable/ Very Valuable	33%	29%	7%
Related Comments	*Distracting, kids online when should be paying attention* *Can make it more complex. Adding another diversion.* *Potentially could help manage learning environment. Have more personalized learning environment: meaningful projects, less discipline problems.*	*Could be a distraction for children* *Could be a useful tool because the students can easily stay engaged using various devices and they are many different options when using technology to control the classroom.*	*I think that managing the environment of a classroom should be done by the teacher not by a device.* *I think that some of the negative behaviour can stem from the use of devices*

Table 8. Recommendations and strategies

Recommendation	Strategy
6. Educational design	Specifically tie the use of mobile devices to course learning outcomes and assignments ● *Perhaps we could incorporate activities and assignments into the course that would force us to use our Tablet more. I found that it was not needed in the classroom therefore I did not bring it with me or use it very much at home either. We could have used the Voice Recorder for self and peer assessment feedback for each assignment.*
7. Appropriate device for the appropriate task	One size does not fit all when it comes to the appropriate use of mobile devices in a blended pre-service teacher education program ● *I personally found my phone was more useful in school placements. It fit into my pocket, was easy to use to take video, pictures, and field notes. On the other hand, I find my laptop more valuable in our university classrooms as it allows me to easily take notes and search for information.*
8. Mobile apps	Ensure that key university apps are accessible ● *It would be handy to have myUniversity as a compatible site with the tablet. From my experience, the myUniversity website doesn't work well/continues to freeze when trying to access my account.* ● *find a way to make Blackboard app available*
9. Tablet devices	Use better quality tablets or our own mobile devices ● *Upgrade the tablets, use something of better quality*
10. Wireless internet connectivity	Improve internet connectivity in the main university building ● *Make sure everyone's device be connected to the internet easily in the classroom*

In the post-study group, the student participants were also asked to comment how they plan to use mobile devices in their future teaching practice. They emphasized that mobile devices should be used as digital tools by K to 12 students for authentic, inquiry-based project work. Many of the study participants had observed these devices primarily being used as eBooks in their K to 12 school placements and they thought that this was an expensive way for students to passively absorb yet more facts and information.

CONCLUSION

This research study was informed by Wenger's (1998) community of practice framework, which emphasizes three participatory dimensions: engagement, accountability, and negotiation. Engagement is dependent on developing an understanding of how to interact with other people within the community such as students and faculty in pre-service teacher education program.

The results from this study demonstrate that students in pre-service teacher education programs potentially have more practical experience with mobile devices than faculty members. Thus, it is prudent for faculty to "listen and learn" from their students about how to use these devices effectively and efficiently.

Becoming accountable to an enterprise, for example a set of program outcomes, prompts members to consider certain possibilities that contribute to aligned perspectives of the world. With regards to the ability of mobile devices to support the learning outcomes of a B.Ed. program both faculty and student participants in this research study indicated that these digital tools could be useful for supporting future professional responsibilities (i.e., career-long learning, collaboration) and facilitating student learning but less effective for planning, assessment, and managing the classroom environment.

Wenger refers to negotiation as the ability to interpret and make use of a repertoire of the community's practice. This form of negotiation corresponds with the Māori concept of *ako* (Barlow, 2001). This term means both to teach and learn. It recognizes the knowledge that both teachers and students bring to learning interactions, and it acknowledges the way that new knowledge and understandings can grow out of shared learning experiences, especially those that are mediated through the use of mobile devices. This concept has been supported by educational research showing that when teachers facilitate reciprocal teaching and learning roles in their classrooms, students' achievement improves (Alton-Lee, 2003). In addition, Hattie (2009) suggests that *ako* is the basis of a visible teaching and learning framework where "teachers SEE learning through the eyes of their students and students SEE themselves as their own teachers" (p.238).

STUDY LIMITATIONS

The two major limitations of this study were the small sample size and the focus on self-reported data. The small sample size (n=20) meant that significance is limited for the analysis of the quantitative survey data and thus, the results cannot be readily generalized or transferred to other pre-service teacher education programs. The surveys, interviews, and focus group conducted in this study all relied on self-reported data, which was limited by the fact that it was only verified by the co-authors of this study. This data may contain several potential sources of bias such as selective memory of the student and faculty participants (i.e., remembering or not remembering experiences or events that occurred at some point in the program) and exaggeration (i.e., the act of representing outcomes or embellishing events as more significant than is actually suggested from other data) (Brutus, 2013).

FURTHER RESEARCH

The findings from this study and the associated research literature (West, 2012) suggest that student ownership of mobile devices in higher education is steadily increasing and that students are expecting to use these devices to support their course and program assignments (BYOD – bring your own device). Thus, further research needs to be conducted in order to determine how students and faculty can effectively use these devices in blended environments to support learning inside and outside of the classroom.

KEY TERMS AND DEFINITIONS

Action Research: A reflective process of problem solving led by individuals working with others in teams or as a part of a "community of practice" to improve the way they address issues and solve problems.

Blended Learning: Integration of face-to-face and online learning methods and technologies.

Bring Your Own Device (BYOD): Policies that permit students to bring personally owned mobile devices (laptops, tablets, and smart phones) to their schools or institutions.

Community of Practice: A group of people who share a common interest and collaboratively work together to learn more about this common interest.

Mobile Apps: A software application specifically designed to run on smartphones, tablet computers and other mobile devices.

Mobile Learning: Learning methods and materials that involve the use of mobile phones or handheld computers.

Tablet Devices: A handheld computer contained in a single panel, which is operated as a touch screen.

This work was previously published in Promoting Active Learning through the Integration of Mobile and Ubiquitous Technologies edited by Jared Keengwe, pages 98-115, copyright year 2015 by Information Science Reference (an imprint of IGI Global).

APPENDIX A: PRE-COURSE STUDENT ONLINE SURVEY QUESTIONS

Important Note: The purpose of this survey is to gather student responses that will help inform the use of mobile devices in the Mount Royal University Education Program. Participation in this survey is voluntary and your responses will be kept confidential. Non-participation in this study will not jeopardize student progress in this EDUC2325: Understanding Current and Emerging Pedagogical Technologies course or the Education Program. Completion of the questionnaire below will constitute informed consent in this *Role of Mobile Devices in a Blended Pre-Service Teacher Education Program?* study. This study has been approved by the Mount Royal Human Research Ethics Board (HREB).

Name: ______________________________

Devices

1. Do you own a mobile "hand held" device (e.g. iPhone, iTouch, Blackberry, Nokia, Motorola, LE, Samsung) that is web-enabled (e.g., can access web sites)?
2. If so, what kind of web sites do you utilize?
3. Do you own a mobile "hand held" device that can take digital pictures?
4. If so, what kind of pictures do you take and what do you do with these pictures?
5. Do you own a mobile "hand held" device that can take digital movies?
6. If so, what kind of videos do you take and what do you do with these videos?
7. What kind of mobile "hand held" device do you own (e.g. iPhone, iTouch, Blackberry, Nokia, Motorola, LE, Samsung)?

Applications

1. Do you have a Google Docs account?
2. Do you have a YouTube account?
3. Do you have a Blog account?
4. Do you have a Flickr account?
5. Do you have a Twitter account?
6. Do you have a Diigo account?
7. Do you have your own personal web site?

B.Ed. Elementary Program

1. How do you think mobile "hand held" devices could be used to support your learning in the B.Ed. Elementary program?
2. What do you think will be the educational advantages of using mobile "hand held" devices in this program?
3. What do you think will be the educational disadvantages of using mobile "hand held" devices in this program?
4. Any other comments or suggestions about using mobile "hand held" devices in this program?

For your future K to 12 teaching career how valuable to do you think mobile "hand held" devices will be for performing the following tasks:

Task	Really not valuable	Not valuable	Not sure	Valuable	Really valuable
6. Planning for learning (e.g. lesson planning)					
7. Facilitating student learning (e.g., different approaches to teaching)					
8. Assessing and evaluating student learning (e.g., marking)					
9. Managing the learning environment (e.g., classroom management)					
10. Working as a professional educator (e.g., career-long learning)					

APPENDIX B: FACULTY INTERVIEW QUESTIONS

Important Note: The purpose of this interview is to gather faculty responses that will help inform the use of mobile devices in the Mount Royal University Education Program. Participation in this interview is voluntary and your responses will be kept confidential. Non-participation in this study will not jeopardize your employment at Mount Royal University. Please sign the informed consent form if you would like to participate in this *Role of Mobile Devices in a Blended Pre-Service Teacher Education Program?* study. You may withdraw from this study at any time and your data will be destroyed. This study has been approved by the Mount Royal Human Research Ethics Board (HREB).

Chapter 22
Soft and Hard Technologies in Technology Education

Kin Wai Michael Siu
The Hong Kong Polytechnic University, Hong Kong & Massachusetts Institute of Technology, USA

Yi Lin Wong
The Hong Kong Polytechnic University, Hong Kong

ABSTRACT

There is a common misconception that technology is limited to physical devices (i.e., hard technology). However, technology also includes soft technology, which is concerned with human and social factors. The emphasis on hard technology has prevented technology education from widening its scope and thus catering to the needs of a changing society. This chapter first briefly identifies the common definitions of soft and hard technologies. It then argues that technology education should emphasize both hard and soft technologies. Through a case study of Hong Kong, the chapter identifies the issues surrounding the inclusion of soft technology in the technology curriculum. The issues comprise the outdated perceptions of the government and schools with respect to technology, teachers' backgrounds, and students' abilities. The chapter then proposes recommendations and suggestions for resolving these issues. The future trend of an all-round and balanced approach toward hard and soft technology in technology education is discussed.

INTRODUCTION

The development of technology education has progressed in line with technological and industrial development over the past few decades (Siu & Wong, 2011). For example, in Hong Kong, plastics and rubber materials have been widely adopted in technology education since the rapid development of the plastics industry in the 1960s. Computers have been widely used in technology lessons since their popularization in the 1980s. In recent years, researchers have begun to understand technology better and their discussions of the topic adopt a wider scope. However, in education, the concept of technology is still often limited to the manipulation of physical devices to solve problems, i.e. hard technology. According to Jin (2011), hard technology is "the technology of controlling the

DOI: 10.4018/978-1-4666-8246-7.ch022

'object'" (p. 25), for example, tools and machines. The limited scope of technology education hinders the potential for further development that might cover technology in its broadest sense.

Technology education should emphasize both hard and soft technologies. Soft technology refers to the technologies that involve human factors (Jin, 2011) and that facilitate human flexibility and initiatives (Norman, 2003). Soft technology emphasizes human needs rather than objects. It is essential to include soft technology in technology education, as students need a wider knowledge of technology to face the technological society of today. The current emphasis on hard technology in technology education may be unable to cater to the needs of a changing society. It is important to educate the next generation with the necessary knowledge and skills of soft technology for a future technological world.

This chapter, which is based on the definition of hard and soft technology provided by Jin (2011), discusses the limitations of the emphasis placed on hard technology in current technology education, and hence argues that there must be a paradigm shift moving away from hard technology toward soft technology. The issue is discussed using the case of Hong Kong. The aims of this chapter are to (1) define soft and hard technologies in the context of technology education, (2) identify the issues through a case study of Hong Kong, (3) identify the needs of soft technology in technology education, and (4) provide suggestions for stakeholders in promoting soft technology to develop a balanced secondary school curriculum.

BACKGROUND

The English word "technology" originated from the Greek word "*tekhnologia,*" meaning "systematic treatment" (Oxford Dictionaries, 2013). It is derived from the ancient Greek notion of "*techne*" (craft) (Reydon, 2012). Technology was associated with any man-made artifacts that were different from natural products. Ancient Greek philosophers believed that there was a fundamental distinction between natural products and artifacts, and that "technology learns from or imitates nature" (Franssen, Lokhorst, & van de Poel, 2009).In this view, artifacts are unable to reproduce themselves whereas natural products are able to reproduce, grow, and change. Obviously, the understanding of technology in ancient Greece focused on artifacts that were distinct from nature, and the purpose of these artifacts was generated to fulfill certain needs. Jin (2011) posited that in primitive times, technology was "the making and use of tools and the utilization of fire and language" (p. 22), which we would regard as hard technology.

In the twenty-first century, the definition of technology has become broader, and is no longer limited to the making and using of tools. The rapid advancement of technology and society has changed how we perceive technology. McNeil (2002) claimed that technology "seeks to find practical ways to use scientific discoveries profitably, ways of turning scientific knowledge into utilitarian processes and devices" (p. 3). Grady (2010) believed that technology is "a way of thinking about a problem, and a way of putting thought into practice" (p. 13). Koelega (1995) claimed that technology "is not only machines or procedures to perform a special task, but also the social and cultural context within which technics are being developed and applied" (Notes section, para. 2). As with our ancestors' perceptions, technology today is still driven by external needs. However, the emphasis on "tools" in primitive times has shifted toward a focus on the ways in which technology is used to tackle problems and produce useful outcomes. The emphasis is no longer on tangible substances, but on ways of thinking and how technology interacts with human minds and knowledge.

The shift in our perception of technology suggests that there may be two kinds of technology: hard and soft technologies. Jin (2011), as mentioned in the previous section, distinguished the two technologies by the object-human dimension. Jin (2011) is not the only researcher to have addressed the issue of the two technologies. Like Jin, Werner, and Bower (2012) also pointed out the different foci of the two technologies in their health guides for health workers in villages. They suggested that hard technology is the technology of things, including "tools, instruments, or machines – that people can make, use, and repair themselves using local resources" (p.15-1).Soft technology, in contrast, is the technology of methods that include "ways of doing, learning, and problem solving that are adapted to people's needs, customs, and abilities" (p. 15-1). Norman (1993) distinguished the two technologies by identifying the different roles of the human. He believed that hard technology "refers to those systems that put technology first, with inflexible, hard, rigid requirements for the human" (p. 232), whereas soft technology is human-oriented, referring to "compliant, yielding systems that informate[1], that provide a richer set of information and options than would otherwise be available, and most important of all, that acknowledge the initiative and flexibility of the person" (p. 232).

Examples of soft technology are plentiful nowadays. The simplest of all is computer software technology. The concept of software is soft technology designed to facilitate communication between the hardware (i.e., the hard technology) and the user. The software interface helps us to operate the hardware so that we are not required to study and understand computer languages. People no longer need to understand such languages to work with computers. Software has also advanced in a way that allows users to choose their preferred interfaces. The flexibility provided by the software enhances the efficiency of the communication between the computer and the user. Software has also combined with other hardware technology to optimize the user experience. For example, some smart phones are able to detect the user's eye motion and pause a video when the user's eyes move away from the screen. This feature integrates hard technology (the eye sensor) and soft technology (the idea of pausing the video) to address human needs.

From the example of human interface design, it is clear that hard technology has been "softening" to cater for human needs, as it seems that hard technology may in itself be insufficient to optimize our lives nowadays. More human factors are involved in technology, and thus there is a shift toward soft technology and away from hard technology (Jin, 2011). However, technology education has been unable to catch up with this trend. The scope of technology in technology education does not currently cover soft technology. This limitation means that students do not have a mindset that favors soft technology. Moreover, some curricular stakeholders may not have sufficient insight to include soft technology in their curriculum planning.

CASE STUDY: TECHNOLOGY EDUCATION AT THE SECONDARY SCHOOL LEVEL IN HONG KONG

In this chapter, the case of Hong Kong is used to examine the inclusion of soft technology in secondary school technology education. Hong Kong has a well-established tradition of technology education at the secondary school level, which can be traced back to the 1920s (Siu, 2008).Design and Technology (D&T) was introduced in 1983 and is the subject most equated with technology education. The D&T curriculum has been revised several times. In the last few decades, it has developed into a subject that requires students to solve the problems of daily life through the creative use of different design skills and workshop techniques. D&T enables students to learn about materials, tools, and machines, and the design, manufacturing, and fabrication processes of products through a number of problem-solving activities (Siu, 2008). Most D&T teachers previously taught woodwork and metalwork in industrial or vocational schools.

The long history and the rich background of technology education in Hong Kong should be able to provide a robust case study.

Hong Kong has a six-year secondary school program. Secondary 1 to 3 is referred to as *junior level* and 4 to 6 as *senior level*. This academic structure was implemented in 2006, and the first cohort left secondary school education in 2012. At junior level, the school subject covering technology education is D&T, and at senior level, it is Design and Applied Technology (DAT). Neither are compulsory school subjects and schools can choose whether to offer the subjects at junior or senior level.

Junior Level

The aim of D&T at junior level is to "develop the technological awareness, literacy, capability and lifelong learning patterns" of the students (Curriculum Development Council, 2000, p.5). Four areas of learning are included in the curriculum: "the nature and impact of technology for yesterday, today and tomorrow," "design and communication," "the tools and machines of technology," and "resources of technology."However, in practice, teachers often place greater emphasis on "the tools and machines of technology."This topic also receives the largest time allocation in the suggested timetable.

A project-based learning approach is often adopted by D&T teachers. Teachers teach the necessary drawing and technical skills through the design process. Wong and Siu (2012), in their study on creativity in D&T projects in Hong Kong, found that the project briefs given to students are often closed and unconnected to the social and cultural background. Students are asked to design and make a defined object or device, such as a stationery stand. Very few human or social factors are considered in the design process and teachers do not expect students to be concerned with human factors at the junior secondary school level. Teachers often focus on the functionality of the artifact. Junior secondary school D&T is limited to learning basic technical skills. Very few teachers emphasize teaching knowledge related to technological literacy and soft technology. This may be due to the perception of D&T as a technical subject in Hong Kong, and because teachers do not want to overload students with too many ideas. Hands-on activities account for most of the curriculum time. This arrangement is also welcomed by most of the students because they can move around in a workshop instead of sitting still in a classroom, which is comparatively more disciplined. In addition, there may not be enough time to allow the students to work on human factors, as the curriculum time for D&T is always shared with other technical subjects such as Home Economics. Volk, Yip, and Lo (2003) also addressed this issue and claimed that the limited curriculum time provides rather superficial coverage of D&T to students.

The practice discussed above implies that D&T at junior secondary school level ignores soft technology. In fact, although the curriculum does include soft technology in topics such as "the nature and impact of technology for yesterday, today & tomorrow," teachers may not be capable of teaching such topics because most of them trained as woodwork or metalwork teachers rather than as D&T teachers when they entered the profession. Teachers are also under great pressure to boost their students' performance in various design and technology competitions to gain recognition from their principals and colleagues. Those students who are able to participate in D&T competitions may have opportunities to explore knowledge beyond their lessons; however, the majority of students does not have this kind of opportunity and may miss out on this opportunity for further learning. In other words, D&T at junior secondary level places less emphasis on thinking, intellectual knowledge, and social awareness.

Senior Level

The DAT curriculum was implemented in 2009.Students are required to study the topics of technology, design, and society in three core strands: technological principles, design and innovation, and value and impact, and to choose another two from the five elective technology studies modules: electronics, automation, creative digital media, visualization and CAD modeling, and design implementation and material process. Schools offer the elective modules according to the availability of school facilities and their teachers' capabilities. The aim of DAT is to "provide students with fundamental knowledge and skills in technology and design, and to cultivate in them the attributes of innovation and entrepreneurship necessary to face the rapid social, economic and technological changes in a knowledge-based economy" (Curriculum Development Council & Hong Kong Examinations and Assessment Authority, 2007a, p. 3). The curriculum and assessment guide for DAT also stated that innovation and entrepreneurship are the two major concepts intended for development.

Social issues and human factors are covered in DAT. An objective of the DAT curriculum is to enable students to become "discriminating, informed and responsible users of products, and develop their awareness of the interplay between technology and aesthetic, enterprise, social, cultural and ethical issues" (Curriculum Development Council & Hong Kong Examinations and Assessment Authority, 2007a, p. 3). The third strand, value and impact, fulfills this objective by focusing on awareness of technological development and its impact on society. In addition, human and environmental factors are included in the first strand, i.e. design and innovation. From the point of view of the curriculum, human factors are covered. However, as suggested by the curriculum document, the compulsory strands only occupy between a third and a half of the curriculum time. The actual time spent on social issues and human factors may not be adequate. Nevertheless, DAT is a new senior secondary school subject and teachers are still exploring better ways of teaching the new material.

At the end of the senior secondary school level, students have to sit a public exam for the Hong Kong Diploma of Secondary Education (HKDSE). A design project accounts for 40% of the total marks in DAT (Curriculum Development Council & Hong Kong Examinations and Assessment Authority, 2007a). As a school-based assessment (SBA), the students have to choose and work on a design project from a project list. The SBA is divided into two parts: Part 1, which comprises research, investigation and data collection (10% out of 40%), and Part 2, which covers the design and making of the project (30% out of 40%). Students must demonstrate their design process, technological understanding, and social and entrepreneurial awareness in their project. In 2013, four projects were offered to students in the SBA project list (see Table 1).

Table 1. Project list of DAT SBA in 2013 (Hong Kong Examinations and Assessment Authority, 2013)

Project	Project Topic	Background Description
1	A flying machine/ system	Energy conservation can help to reduce a future shortage of oil in the world.
2	Furniture with special features	Furniture can be designed specifically for people with individual needs by adding special features.
3	Strategic landfills	Every day, thousands of tons of garbage from businesses, industry, and households need to be disposed of.
4	A topic of your choice	This topic requires the approval of your school teacher.

Projects 1 and 3 are related to energy conservation and garbage disposal. Project 2 is related to individual needs. It is obvious that the design projects in the SBA project list are related to human or social factors. However, in project 4, the extent to which students consider human factors in their design greatly depends on the nature of the topic they have chosen.

Teachers and students at senior secondary school level are under great pressure due to the public examination, which directly affects their future prospects. Thus, it is unsurprising that learning and teaching activities are based on the examination. If the projects suggested in the SBA project list involved human and social factors, teachers would undoubtedly encourage students to learn more about this aspect of technology.

THE INCLUSION OF SOFT TECHNOLOGIES IN TECHNOLOGY EDUCATION

The development of technology started when humans first made and used artificial tools to optimize their lives (Jin, 2011). Technology in primitive times focused on tools to effectively help humans to solve daily problems. As civilization and the economy progressed, technology became a tool to increase efficiency and maximize profits. However, although investment in technology benefits the economy, it also creates problems for humans. Bill Joy, the cofounder and chief scientist of Sun Microsystems, has claimed that some of the most powerful technologies threaten human lives and even our existence, and that scientists and technologists sometimes fail to understand the consequences of their inventions in the process of discovery and innovation (Joy, 2000).It can be argued that the emphasis of technology development has been placed solely on hard technology and that inventors have been less concerned with human and social factors. This attitude may be practical and applicable for a society experiencing rapid industrial development but it is not suitable for a world that is dominated by post-industrial societies. People today care more about quality of life, and therefore, technology should focus on the improvement of our living experience and not just efficiency and profits.

Particular technologists and technology companies may be aware of this issue and gradually shift their emphasis from hard to soft technology. The inclusion of soft technology in technology education has become an essential task if educators desire to educate the next generation for the world of the future. However, technology education does not currently include adequate knowledge of soft technology in the curriculum. Wicklein (1997), in his review of the focus of the curriculum for technology education, has also addressed this issue and has pointed out that educators are primarily concerned with the technical procedures for making artifacts instead of the human and social factors involved in technology. Using the case study of D&T in Hong Kong, we identify several potential issues at different levels of curriculum planning and implementation.

Government

Stakeholders in curriculum planning at the government level may not have the insight to realize the importance of soft technology in technology education, because technology education is derived from traditional woodwork and metalwork, which focus on skill training. Zuga (1997) analyzed technology education in the United States based on a historical review and found that historical factors may limit the further development of technology education. The situation in Hong Kong is similar, and this limitation may prevent technology education from widening its scope to soft technology. Curriculum development officers in the state's education department should break the traditional boundaries and introduce more soft technology alongside the existing hard technology. However, this would not be a trivial task. For example, in

Hong Kong, curriculum development officers are often experienced D&T teachers and most of them have already formed their ideas of what D&T is. As long as there are no young scholars or other parties contributing to the team, it will not be easy to introduce new ideas to the curriculum. All of this may be reflected in the current junior secondary school curriculum. However, for the new senior secondary school DAT curriculum, the Education Bureau (EDB) of Hong Kong has invited the Institute of Professional Education and Knowledge (PEAK) of the Vocational Training Council (VTC) to develop the DAT resource materials (see Curriculum Development Institute, 2009). It is clear that the new senior secondary school curriculum will make greater reference to human and social factors.

In fact, in the Hong Kong curriculum, soft technology is referred to not only in technology education but also in other school subjects. The curriculum development officers of liberal studies were aware of the importance of soft technology and included knowledge of soft technology in liberal studies. Liberal Studies in Hong Kong is a cross-disciplinary subject that comprises three areas of study: self- and personal development, society and culture, and science, technology, and the environment (Curriculum Development Council& Hong Kong Examinations and Assessment Authority, 2007b). Most of the knowledge of soft technology is in the area of science, technology, and the environment. Although this arrangement allows students to acquire the necessary knowledge, it would still be better to situate this knowledge in the context of technology education so that students can understand its content in the real-life practical context of DAT.

Schools

The school principal and other administrative personnel in a school may not have up-to-date knowledge of technology. Wright, Washer, Watkins, and Scott (2008) conducted a survey with the stakeholders of technology education in the United States and found that nearly half of the surveyed stakeholders, including school principals, teacher educators, and technology teachers, believed that career and technical education is the primary purpose of technology education. Principals may still view technology education as a craft-based or skill-based subject. While they are planning the school curriculum, their perceptions may affect decisions on the curriculum time allocated for technology education. They may limit the curriculum time to the minimum, as it is generally accepted that craft skills are less important in a knowledge-based economy and society. In fact, Herschbach (1995) cited Frey's (1989) belief that craft skill is the lowest level of technological knowledge. If principals consider technology education to be solely related to craft skills, it is unsurprising to find that technology education does not occupy much curriculum time in the school timetable. For instance, in Hong Kong schools, time limitations mean that students are often unable to study D&T for an entire academic year at a time.

Because of the time constraints, teachers cannot teach technology in depth. Schools do not employ large numbers of D&T teachers to cover the subject. Thus, there is virtually no support for D&T teachers. For schools that only offer D&T at junior secondary school level, it is questionable whether they can provide adequate support for teachers and students to learn about soft technology. However, schools that offer DAT have a better teaching environment, as DAT is one of the examination subjects in DSE. Schools need to give support to teachers and students so that students can excel in the public examination.

Technology Teachers

As mentioned in the previous section, most teachers may not be capable of teaching soft technology because of their traditional training. They are skilled in hands-on work but may not be equipped to teach about social issues. Moreover, some may not have the vision to realize the importance of soft technology. In fact, the teaching strategies used to teach practical skills, hard technological knowledge, and human issues are different. Hill (2006) pointed out that technology education is "action-based" and always has "hands-on instructional activities" (p. 55). The same strategies may not be applicable in teaching human and social issues. Johnson (2010) addressed a similar issue by arguing that teaching ethics in science may need a different and specific teaching strategy. It is thus not easy for these in-service teachers to learn new teaching strategies or even to adopt another teaching style to teach related human issues effectively. It is demanding to require technology teachers to be knowledgeable about science and technology and also social science, if soft technology is taken into account in the curriculum.

The demands of technology teachers have been reflected in Hong Kong DAT. DAT teachers are required to teach technology, design, and entrepreneurial knowledge so that the students can finish their projects. Although the students are told to research and develop their designs by themselves, the teachers also need to possess the knowledge to guide the students through the process of designing and making.

Students

Although knowledge of soft technology is best situated in technology education, it is questionable whether students are capable of learning and applying soft technology in a real-life context. Some students may be unable to acquire knowledge of both hard and soft technology, as the scope is much wider compared with hard technology alone. Therefore, it can be argued that technology education with both hard and soft technology favors students with higher academic ability. Students with lower academic ability may not be able to master such knowledge thoroughly. In Hong Kong, because of the history and the image of D&T in society, students with higher academic ability tend not to take the subject at senior secondary level. Yau and Ong (2008) reported a similar situation in Singapore, where the subject is not popular among academically inclined students, who are generally encouraged to take academic subjects that are better received by the various departments and faculties of universities. In contrast, students with lower academic ability are encouraged to take DAT because it seems that the subject does not require high language ability. In this regard, the inclusion of soft technology in DAT may be too broad for DAT students in Hong Kong.

SUGGESTIONS AND RECOMMENDATIONS

In consideration of these issues, some suggestions and recommendations at the different levels of curriculum planning and implementation are proposed, primarily based on the context of Hong Kong. Some of these suggestions and recommendations are also applicable in other contexts, as they not only tackle the specific problems and issues in Hong Kong, but could also optimize any technology education curriculum.

It is noted that the suggestions and recommendations proposed for the government, schools, and technology teachers in this section may not correspond to the sub-sections with the same title in the previous section because some of the issues addressed in the previous sub-sections may be solved or settled by other parties in the education system. Therefore, the subsequent suggestions and recommendations may be placed under sub-sections with a different title.

Government

In view of the inadequacy of the inclusion of soft technology in the technology education curriculum, especially at the junior secondary level, and the traditional educational background of curriculum development officers, school principals and teachers, curriculum development officers should first update their understanding of technology so that they can reflect the needs of professional development officers and thus provide adequate training and education, e.g. advertisement, to in-service teachers and the public. Curriculum development officers must lead the curriculum, especially the junior secondary school curriculum, to a new way of thinking that includes knowledge of soft technology. Nkosana (2008) believed that curriculum officers are important, as they provide leadership to teachers and supervise the development of the curriculum. The success of the implementation greatly depends on the attitude and perceptions of the officers. Therefore, it is important for them to be inspired and to be aware of the importance of soft technology. They may need to refer to the technology education curriculum in other countries so that the depth and breadth of the Hong Kong curriculum can be accurately assessed.

The government should then provide adequate training courses for in-service teachers to update their knowledge of and perspectives on technology education. Fraser, Kennedy, and Reid (2007) also affirmed the importance of teachers' continuing professional development around the world. In Hong Kong, providing diploma courses for teachers would also be feasible, as the current teacher training model does not include any further enrichment courses for technology teachers. Optimizing the education of technology teachers is essential for ensuring that teachers have more opportunities to get equipped for teaching new contents.

Furthermore, the government may also publish advertisements for the new technology curriculum so that stakeholders can understand more about the shift of the technology curriculum and soft technology. As Morris (1996) stated, "the government has the ultimate responsibility for all aspects of schooling" (p. 110), so it is important for the government to take control of this issue.

School

Because knowledge of soft technology exists not only in technology but also in other school subjects, as mentioned in the previous section, a school can encourage teachers to work in collaboration with other teachers in the same school or even other schools in the same district. Schools could support teachers and provide opportunities and resources to help teachers to collaborate between different subjects. School subjects such as science, mathematics, and liberal studies can cooperate with D&T and DAT so that students' school time can be used more effectively and more support can be given to D&T or DAT teachers. In this way, the subject boundaries can be blurred and students can acquire knowledge that is transferable and applicable to different contexts. Wicklein and Schell (1995) also advocated the integration of mathematics, science, and technology education so that students need not be forced to reconnect knowledge learned outside the classroom. Wraga (2009) also stated that an interdisciplinary approach or the integration of curriculum could create "the cumulative impact of all learning experiences" (p. 92), help students to understand the complex interrelation between these experiences, and relate and apply subject knowledge to social issues. Collaboration between subjects is surely beneficial to technology education, particularly if soft technology is included. Soft technology is a form of cross-disciplinary knowledge that may also include, but not limited to, human behavior, psychology, and social issues.

In addition, the schools within a district can form a network for exchanging teaching resources. Wheeler (2001), in his study of the role of the teacher in information and communication technologies, also advised teachers from different schools to work together and to share resources to maximize their value. Teachers may then be able to save time for preparatory work and to lighten their workload. The resources should not be limited to teaching materials but should also include human resources. Teachers from different schools can form co-teaching groups so that students can benefit not only from teachers in their own schools but also those from neighboring schools. DAT follows this practice in some districts in Hong Kong. However, this involves many problems in cooperation and administration.

Technology Teachers

Technology teachers should take the initiative and optimize the curriculum by providing feedback to schools and the government. In the teaching profession, teachers tend to follow instructions from the education department and seldom have a role to play in curriculum planning at the governmental level. Teachers are rather passive in this regard. Ingersoll (2003) also addressed the passiveness of teachers and pointed out that "teachers in American schools had far less input into how their schools operated and what their jobs were to be" (p. 2). Perhaps teachers' heavy workloads do not leave them with the necessary time to rethink the curriculum. Furthermore, Esteve (2000) addressed the issue of teachers' excessive workloads, which mean they can only put limited effort into their tasks. The inadequacy of school support also causes teachers to contribute extra time to their teaching tasks. This lack of time and support reduces their initiative to add new teaching components and corresponding teaching methods to the curriculum.

However, to optimize the curriculum, teachers must take the initiative and spend time on rethinking and optimizing the curriculum, because they are the experts who implement the curriculum and the group that understands their own and their students' immediate needs. Subsequently, in the dilemma between the lack of spare time and taking the initiative, teachers and the technology teacher union should speak out and explain the situation to their schools and the government to make space for them to facilitate the optimization of the curriculum.

FUTURE TRENDS

Technology has advanced to such a stage that we no longer ask how technology works but why it was invented and what are the consequences of using it. Focusing on hard technology in technology education may not be appropriate. The inclusion of soft technology in the curriculum has become essential, and the current focus on hard technology may is unable to provide a broad perspective for students in the changing technological world. In addition, technology education should include the teaching of morality and values. Without this responsibility, technology education is degraded to a kind of craft-based training.

However, this does not imply that the emphasis should solely be on soft technology and that hard technology should be omitted. A balanced approach should be promoted so that students can understand and articulate both hard and soft technologies. Students should not only master the skills of technology but should also understand the values behind the technology. This kind of all-round and balanced approach should be sought, and represents the aim of technology education in the future.

Soft technology is an important component in technology education. Learning and teaching technology should not be limited to the functionality and feasibility of technology but should also include human and social factors. The curricula of school subjects such as D&T or DAT should respond to this necessity. Yet technology education that includes the consideration of these factors is not intended to replace humanities subjects. In any event, it is not possible to take over the role of humanities subjects, as these subjects have a wider coverage related to social issues. Similar to the collaboration between science, mathematics, and technology, technology should also cooperate with other humanities subjects such as liberal studies so that knowledge can be transferred to students effectively without overlapping. More important is the depth and breadth of the knowledge of soft technology and its cooperation with other humanities subjects.

Conducting research is essential to developing an all-round and balanced approach to technology education. However, educators and researcher soften focus on learning and teaching hard technology instead of soft technology. There is an urgent need for related research on soft technology. For instance, the performance, motivation, and perceptions of students toward learning soft technology need to be explored as these topics are essential to the development of the curriculum. The results of such studies will enable educators to fine-tune the direction of the learning and teaching of soft technology.

CONCLUSION

In primitive times, technology was involved making and using tools (Jin, 2011). As technology advances, technology is no longer limited to tangible tools. Nowadays technology focuses on the way of thinking and how it interacts with the human (Grady, 2010; Koelega, 1995). Human and social factors are becoming more important in technology, as an over-emphasis on hard technology may cause problems. The importance of soft technology is highlighted by the changing technological world and there is an urgent need for technology education to include knowledge of soft technology in its curriculum, as the current emphasis on hard technology lags behind the change.

However, it is questionable whether technology education currently includes soft technology in its curriculum. Our case study of Hong Kong revealed that knowledge of soft technology is only included in DAT, i.e., at senior secondary school level. There is only minimal coverage of soft technology in D&T at junior secondary school level, primarily because of the government's and schools' outdated perceptions of technology, the teachers' backgrounds, and the students' abilities. Encouragement from the government and cooperation between schools, technology teachers, and teachers of different school subjects is suggested so that the inclusion of soft technology can be made possible.

The inclusion of soft technology is a future trend in technology education. Technology educators should ask for an all-round and balanced approach that includes both hard and soft technology in the curriculum to develop students' technology literacy. Soft technology is not only a form of knowledge but also a kind of mindset that facilitates the use of hard technology. However, it is recognized that the recommendations and suggestions proposed in this chapter are challenging. Different parties involved in the curriculum development of technology education need to compromise before a consensus on the issue can be achieved. Nevertheless, it is hoped that soft technology can be promoted and that the next generation may use technology more wisely to benefit society and the world of the future.

ACKNOWLEDGMENT

We would like to acknowledge the project funding for the study and preparation of this chapter supported by The Hong Kong Polytechnic University. We also thank the visiting research fund of Massachusetts Institute of Technology for supporting the preparation of this chapter.

KEY TERMS AND DEFINITIONS

All-Round and Balanced Approach: All-round and balanced approach is the suggested approach that includes both hard and soft technologies as appropriate in the technology curriculum.

Curriculum: The curriculum includes the aims, objectives, teaching content, teaching strategies, assessment methods, and other components of learning and teaching in classrooms.

Design and Applied Technology (DAT): DAT is the senior secondary school subject of technology education in Hong Kong. It is an extension of D&T. It enables students to learn innovation and entrepreneurship in a knowledge-based economy through a number of problem-solving activities.

Design and Technology (D&T): D&T is the junior secondary school subject of technology education in Hong Kong. It enables students to learn about materials, tools, machines, and the design, manufacturing, and fabrication processes of products through a number of problem-solving activities.

Hard Technology: Hard technology refers to the technological knowledge related to technical devices and procedures and the controlling of technological devices.

Soft Technology: Soft technology refers to the area of knowledge that concerns human and social factors in a technological context.

Technology Education: Technology education is the study of technology. Students learn technological and design knowledge and processes in technology education.

ENDNOTES

1. According to Norman (1993), the word "informate" was invented by Sushana Zuboff in *In the Age of the Smart Machine*. It is used to "describe the potential of new technologies to inform, to provide people with rich access to a variety of information that would not be available without technology" (p. 226).

This work was previously published in a Handbook of Research on Education and Technology in a Changing Society edited by Victor C. X. Wang, pages 625-638, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

Chapter 23
Use of Tablet Computers and Mobile Apps to Support 21st Century Learning Skills

Michael Reichert
University of Delaware, USA

Chrystalla Mouza
University of Delaware, USA

ABSTRACT

In this chapter, the authors provide examples that illustrate ways in which educators can use tablets and mobile apps to redesign school experience in order to support individualized instruction, development of 21st century skills, and anytime anyplace learning. These examples are generated from a two-year examination of a tablet initiative in a private all-boys school. Using insights from human-centered views of mobile learning, the authors highlight interactions among mobile apps, learners, and peers, while examining issues of pedagogy associated with the implementation of mobile learning. They conclude with implications for researchers, educators, and practitioners involved in the implementation of mobile initiatives.

INTRODUCTION

Andrew, a 13-year old 8th grader, walks into his social studies class. Upon entering, he unlocks his iPad, opens up *Edmodo* and begins his warm-up as he does each day the class meets. For today's warm-up, the teacher is asking students to consider the major reason U.S. President Kennedy did not get along with U.S.S.R. Premier Khrushchev, a lesson covered in the previous night's online lecture delivered by the teacher through *Voicethread,* consistent with a flipped classroom approach. To help form his response, Andrew is able to cue up a Cold War video the teacher linked from the *History Channel* app to the warm-up post. "Three minutes left on the warm-up," the teacher says as he walks around the room monitoring student work. Andrew takes the teacher's cue, as it is time to write his response in *Edmodo*. As students enter their posts in *Edmodo*, the teacher updates the responses and makes note of those students who are able to respond accurately and those who appear

DOI: 10.4018/978-1-4666-8246-7.ch023

to struggle. The teacher uses this information as a form of formative assessments to better gauge which students need extra support and differentiate his instruction accordingly.

Andrew's story described above illustrates a way of embracing mobile learning and opening up new learning opportunities that prepare students for 21st century skills required to work and function in an increasingly mobile and information rich society. According to the latest issue of the New Media Consortium Horizon Report (Johnson, Becker, Cummins, Estrada, Freeman, & Ludgate, 2013), mobile learning is rapidly becoming a key component of K-12 education with the potential of near-term adoption. Mobile learning has been initially defined as learning where the dominant technologies used are handheld or palmtop devises (Trexler, 2005). In recent years, however, scholars have moved from *device-oriented* to *human-centered* definitions of mobile learning where the focus is primarily on learners and context (Koole, 2009; Laouris & Eteokleous, 2005; Sharples, Taylor & Vavoula, 2007). Koole (2009), in particular, proposed the Framework for the Rational Analysis of Mobile Education (FRAME), which includes a combination of the interactions between learners, their devices, and other people. In this framework, mobile learning provides increased access to information, enhanced collaboration among learners, and a deeper contextualization of learning (Koole, 2009). According to van't Hooft (2012), this model is valuable in K-12 education because it allows us to consider mobile learning devices, pedagogy, and curriculum in a holistic way.

The introduction and wide adoption of mainstream tablet computers in the last three years has re-energized and extended inquiry into the affordances of mobile learning in education (Brand & Kinash, 2010). More specifically, the introduction of the Apple iPad in 2010 as well as the dramatic growth of mobile educational applications (apps), software programs that run on mobile devices, have redefined what we mean by mobile computing and expanded the capabilities of mobile devices enormously (Johnson et al., 2013). In order to take advantage of the affordances and capabilities of mobile devices and mobile apps, however, educators need to redesign school experiences in order to support: (a) individualized instruction (Squire, 2012); (b) development of 21st century skills - the ability to access and evaluate information, create and innovate, communicate in new ways, and collaborate effectively (Partnership for 21st Century Skills, 2009); and (c) anytime anyplace learning through multiplicity of space (Squire, 2012).

In this chapter we provide examples that illustrate how educators can use iPads and mobile apps to support such learning experiences. The examples are generated from an examination of an iPad initiative in a private school in a Mid-Atlantic State launched in 2011. Specifically, the examples are generated from the first author's classroom (Michael), who has served as a social studies teacher at the school since the inception of the initiative. Using insights from *human-centered* views of mobile learning, we analyze these examples paying close attention to the interactions between learners, iPads and other people as suggested by Koole (2009). We also examine issues of pedagogy associated with the implementation of mobile learning and its potential to support the development of 21st century skills. Finally, we discuss implications of our work for researchers, educators, and practitioners involved in the implementation of iPad initiatives.

BACKGROUND

There is no doubt that the emergence of tablet devices such as the iPad has taken the educational community by storm. The Los Angeles school system, for instance, has recently approved the purchase of $30 million worth of iPads, while districts from Texas to Chicago and Florida are instituting iPad initiatives worth millions of dollars. Further, current estimates indicate 70 billion app downloads in 2013, with educational apps being the second most downloaded in iTunes of all categories (Johnson et al., 2013). Despite the wide adoption of tablets and mobile apps, there is scarcity of research that examines the use of these technologies in teaching and learning, particularly the ways in which they are used to transform the quality of teaching and learning and blend face-to-face with virtual space (Brand & Kinash, 2010).

iPads and Mobile Apps to Support Teaching and Learning

Although empirical literature examining the use and outcomes of iPads and mobile apps in K-12 settings is still scarce, some evidence has begun to emerge on their potential to enhance teaching and learning. Using the camera app available on most mobile devices, for example, White and Martin (2014) and Ekanaykae and Wishart (2011) examined the role of photographic images taken by students to mathematize commonplace objects and capture authentic materials related to scientific experimentation. Findings indicated that photographic images captured on mobile devices enabled teacher planning and supported student learning by promoting their observation skills and creating opportunities for collaborative discussion.

Hutchison, Beschorner, and Schmidt-Crawford (2012) examined the viability of iPads and mobile apps to support and enhance literacy instruction and foster the acquisition of skills required to read and write in digital environments. Examining the work of an elementary literacy teacher over a period of three weeks, Hutchison et al. (2012) found that the use of iPads not only helped the teacher meet her print-based literacy goals but it simultaneously introduced students to new literacy skills associated with 21st century technologies including the ability to communicate and visualize information using apps such as *iBooks*, an app for downloading and organizing books and *Doodle Buddy*, a drawing and doodling app.

Looking at the integration of iPads specifically for social studies, Berson, Berson and McGlinn Manfra (2012), described the practice of a third grade teacher who used iPads to facilitate students' discovery of cultural differences and similarities between the lives of children in Florida and Haiti. The authors noted that the use of iPads in conjunction with apps that supported creativity, collaboration, and communication not only captured student voices but it also promoted increased excitement and engagement among students, served as a means for furthering classroom community building, and promoted social studies learning goals.

In one of the most comprehensive efforts to review the impact of iPads on teaching and learning, Heinrich (2012) examined the implementation and outcomes of a one-to-one iPad initiative at a non-selective secondary school in England for students ages 11-18. Findings indicated that the iPads were well received and used increasingly within the curriculum reflecting pedagogical changes and new ways of learning that took advantage of anytime anyplace access. Further, the iPads had a positive impact on student motivation and ability to communicate, collaborate, and conduct research. Heinrich argues that their outcomes clearly demonstrate the value of the iPad as an educational tool.

These examples demonstrate ways in which mobile devices and educational apps can support teaching and learning. The use of the camera app allowed students to personalize their learning and situate it within real world examples. Similarly, the use of content focused and communication apps supported the development of traditional and 21st century learning skills while promoting collaboration and social interaction. Nevertheless, these examples also demonstrate the role of the teacher in orchestrating the use of mobile devices and educational apps. Murray and Olcese (2011), for example, found that the majority of the apps currently available are not consistent with modern theories of learning and skills needed to compete in a 21st century economy. Further, the majority of educators continue to rely on behavioral models of teaching rather than collaboration and knowledge construction in a social context as advocated by human-centered views of mobile learning. As a result, teacher preparation and willingness to design experiences that capitalize on the affordances of mobile devices is critical (Kukulska-Hulme, Sharples, Milrad, Arnedillo-Sanchez, & Vavoula, 2009).

iPads and Mobile Apps to Blend Face-to-Face with Virtual Space

Recent data from the Pew Research Center indicate that mobile access to the Internet among teens is pervasive (Madden, Lenhart, Duggan, Cortesi, & Gasser, 2013). Specifically, 47% of teens have a smartphone while 23% have a tablet computer, a level comparable to the general adult population. Further, one in four teens access the Internet mostly using their phone. With students increasingly spending more time on the Internet through the use of mobile devices, schools are beginning to embrace hybrid-learning models that have the potential to blend face-to-face with virtual space and leverage the online skills students already develop outside of school. Such efforts are supported by the increased availability of open content on the Internet – educational materials that are "freely copiable, freely remixable, and free of barriers to access, sharing, and educational use" (Johnson et al., 2013, p.7).

One particular approach garnering increased attention for helping learners blend face-to-face with virtual space using mobile devices and open content is the flipped classroom. The flipped classroom uses educational materials on the Internet, including audio and video often delivered by experts and teachers, as a primary content strategy. In the flipped classroom model what is typically done in class and what is typically done as homework is inverted or flipped. As a result, students can use their mobile devices at home to read relevant materials, listen to an audio or video lecture, or work on a set of problems before coming to class and then use class time in active learning such as labs, games, simulations or other discussion oriented activities (Freeman Herreid & Schiller, 2013).

As Bergmann and Sams (2012) describe, the flipped classroom model speaks the language of today's students who grew up with access to the Internet, YouTube and other digital resources. The use of the flipped classroom in conjunction with mobile devices helps students move at their own pace and use technology in flexible ways consistent with 21st century learning. While students watch a flipped lesson at home, for example, they now have the ability to pause, write down important information, and rewind when they need to review the content again (Bergmann & Sams, 2012). In essence, through the flipped classroom approach, students actively differentiate lessons to allow for deeper understanding of the materials. Indeed, teachers using this method reported seeing increased levels of student achievement, interest, and engagement (Fulton, 2012). Further, along with acquiring deeper understanding, students working in flipped classrooms can develop the ability to problem solve by collaborating on authentic learning tasks with their peers (Hoy & Hoy, 2013)

MAIN FOCUS OF THE CHAPTER

Context of this Work

In this chapter we provide examples of how access to networked tablet devices and mobile apps can help create new models of teaching and learning in K-12 settings that support the development of 21st century skills. These examples are drawn from a one-to-one iPad initiative initiated in 2011 in a private school in a Mid-Atlantic state. The school includes only boys in grades PreK-8. The initiative was instituted at the middle school level, which enrolls boys in grades 6-8. At the onset of the initiative, the school enrolled 101 middle school boys: 6th grade (n=40), 7th grade (n=28), and 8th grade (n=33). The school purchased iPads from Apple and students then purchased their device from the school. Each student was responsible for covering the cost of the iPad, which was built into the school's tuition cost, and was allowed to carry the iPad to school and at home. Students created their own iTunes account and were provided with iTunes purchasing cards for fee-based apps. All students reported having wireless Internet access at home, which was important given that iPads were only equipped with wifi.

Technology has always been an important part of the school's curriculum beginning in kindergarten. Students in grades K-4 have access to a computer lab and desktop computers in the classroom and those students are expected to acquire basic technology literacy skills (e.g., saving documents, navigating online resources, etc.). Prior to the iPad initiative technology was fully integrated in grades 4-8 primarily through access to laptop carts. Students in upper grades learned to utilize Web 2.0 tools to communicate through podcasting, wikis, and blogs and other types of digital tools.

As the laptop carts aged, administration decided to move into a one-to-one tablet direction based on a cost analysis as well as similar initiatives instituted to private area high schools in which most boys graduated to after their middle school years. Further, middle school teachers expressed interest in utilizing tablet devices for instructional purposes.

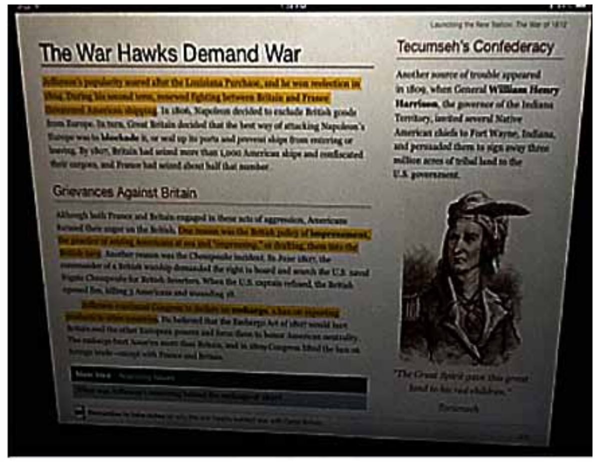
The initiative was rolled out during the summer when all middle grade teachers received their own iPads and participated in professional development offered by Apple. This initial exposure was followed by weekly faculty iPad meetings at the school throughout the school year often attended by two University faculty who assisted the administration and the teachers work out pedagogical strategies associated with effective use of networked mobile devices. To further familiarize teachers with resources and strategies for effective use of iPads a second full-day of professional development was offered during a designated in-service day where a University professor helped teachers through topics such as collecting and organizing content on the iPad, digital storytelling, multitasking and productivity, lesson planning, and authoring.

At the initial stages of the initiative, administrators and teachers identified a range of versatile apps that could be used across content areas. A concerted effort was made to identify apps free of charge whenever possible. The initial set of apps included among others: (a) *iHomework* for helping students keep up with their homework, grades and other school related information; (b) *Camera Roll* for managing photos and images; (c) *iBooks* and *Kindle* for reading materials on the iPad; (d) *Evernote* for note-taking; (e) *Pages* for word-processing; (f) *Keynote*, *ShowMe* and *Doodle Buddy* for presentation purposes; (g) *Dropbox* for managing documents; and (h) *Edmodo* for learning management and classroom networking. This decision intended to familiarize all teachers and students with a common set of apps that could be used in a variety of contexts prior to moving to more specialized, content-specific apps. At the end of each year, teachers met to reassess the effectiveness of the apps, updating the list yearly based on their implementation experiences.

Over time, and multiple trials, the school settled on a framework for reviewing additional apps, which emphasizes productivity and communication. Specifically, a set of themes that cut across selected apps characterize the framework including: (a) ability to individualize student learning; (b) support for multiple media such as audio, video, and text; (c) ability to foster communication and interaction; (d) minimal or no cost; and (e) availability as both a stand-alone app and on the Internet.

In this chapter we present examples from Michael's class over a 2-year period, which illustrate the ways in which iPads and mobile apps can be used to individualize instruction, support 21st century learning skills, and promote anytime anyplace learning.

Figure 1.



Use of iPads and Mobile Apps to Individualize Instruction

In today's classrooms there is an increased demand for education that is customized to students' diverse needs, allowing learner choice, control and differentiation (Johnson et al., 2013). In this section we provide two examples of how mobile media can individualize students' learning experiences. In particular, we discuss the use of *iBooks* and *iBooks Author* apps as well as *ShowMe* app.

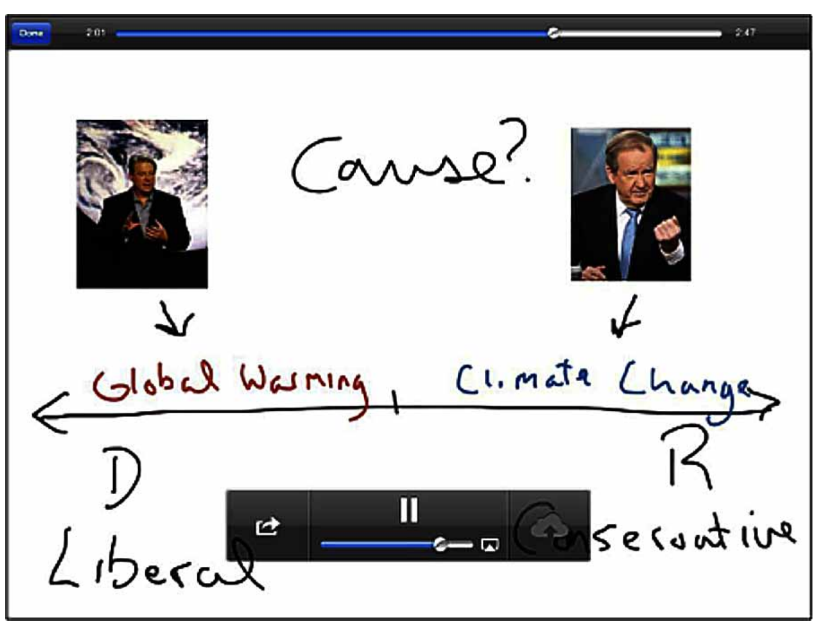
During the 2012-2013 year, the school purchased a U.S. History *iBook* for students in seventh and eighth grade (see Figure 1). Signaling a shift from traditional print-based textbooks, the use of *iBooks* enabled students to personalize their reading experience and make text "come alive". Often typical of high quality electronic textbooks, the U.S. History *iBook* included a range of interactive features. Each chapter began with a video and audio summary both of which introduced the topic and the essential questions. Following the introduction, the *iBook* included an interactive timeline that helped students visualize where the particular topic fit in the big scheme of American History. The timeline visualization helped students situate the particular topic in context. Further, each section included an audio summary of key issues as well as a five-question assessment embedded into each chapter that helped students gauge their understanding of what they had just read.

In addition to those built-in features, by using their iPads students were able to take advantage of features generic to the *iBooks* app to physically interact and manipulate the text, personalizing their reading experience. For instance, students could tap specific words with their fingers to get definitions and instant access to a dictionary, as well as interactive images such as maps that zoomed in to further explain important areas. Further, students could physically highlight text with their fingers and type notes, which were automatically cataloged by page number and section then stored within the framework of the *iBook*. The use of such features, available at the students' fingertips made the reading experience more individualized, interactive, and engaging (Larson, 2010).

In 2012, Apple also rolled out an Application for the MacBook, called *iBooks Author*. *iBooks Author* allows users to publish their own books complete with interactive features such as those listed above. Using *iBooks Author*, Michael was able to "package" social studies units and notes, and is planning on using them during the current academic year. Essentially, the use of *iBooks Author*, allows instructors to individualize reading materials for their own students and context rather than rely on print-based textbooks or notes. Similarly, *ShowMe* app (see Figure 2) allows the teacher to individualize not just reading materials but a range of instructional materials for students by turning the iPad into a personal interactive whiteboard. *ShowMe* app allows users to record voice-over, add pictures or draw their own images, and explain a range of topics through tutorials or personalized messages and commentary. *ShowMe* products can subsequently be shared online and can be accessed by members of the *ShowMe* community. *ShowMe* provides a useful companion to flipping the classroom by allowing teachers to share their own interactive materials with students. For example, Michael used *ShowMe* to record a video describing a simple political spectrum. Consistent with the flipped classroom model, his students watched the video as homework. Although there is a range of apps that use similar features, Michael chose *ShowMe* because he found it easy to use and enjoyed having access to the recordings from any mobile device or on the Internet.

In Michael's class students used the *ShowMe* app both within the classroom and as a home exercise. Since *ShowMe* products can be accessed by users through a unique URL, Michael was able to embed his *ShowMe* materials into social networking spaces created specifically for students in his class. Michael, in particular, used *ShowMe* to explain content specific vocabulary, present new materials, and discuss charts or graphic essentials. For example, rather than spending multiple class periods reviewing map skills with students such as latitude, longitude, Prime Meridian, Equator and the hemispheres, Michael recorded a short lecture using *ShowMe*. For this particular lesson, *ShowMe* enabled Michael to condense a 45-60 minute teacher-centered lecture into a 5-10 minute *ShowMe* presentation specifically for students in his own class. Students reviewed and interacted with the *ShowMe* at home, using a flipped classroom approach. Subsequently, students spent the class time freed up drawing maps of various locations, therefore applying their new skills into practice and illustrating whether they have truly learned the concept. By having students review

Figure 2.



the materials at home or on the go on their iPads, Michael takes advantage of his freed class time to meet with students individually or in small groups, assess whether they have mastered the task and provide personalized remediation when appropriate.

In addition to Michael using *ShowMe*, students themselves also use *ShowMe* to create their own presentations and materials for selected topics. In turn, Michael uses *ShowMe* products as informal assessments because they allow him to visually see which students have mastered a concept and are ready to progress to the next.

Use of iPads and Mobile Apps to Support 21st Century Skills

In this section, we present examples of pedagogical practices that utilized iPads and mobile apps to support the ability to access and evaluate information, create and innovate, communicate in new ways, and collaborate effectively.

Mobile Apps to Support Access to Information

One of the great benefits of networked mobile devices is their ability to empower users with instantaneous access to information serving as amplification devices (Squire, 2012). It was not difficult to witness that in Michael's class. When student received their iPads they found great joy in trying to confirm factual information included in Michael's presentations by researching the topic on the Internet. If they ever appeared to find something that did not seem entirely accurate to them, they proudly pointed their finding to Michael. It did not take long for Michael to realize that the students enjoyed this game – not because they were able to point out to the teacher potential errors, but because they enjoyed their newfound power of having a wealth of information literally at their fingertips. This power seemed to level the playing field providing both the students and the teacher with equal access to information.

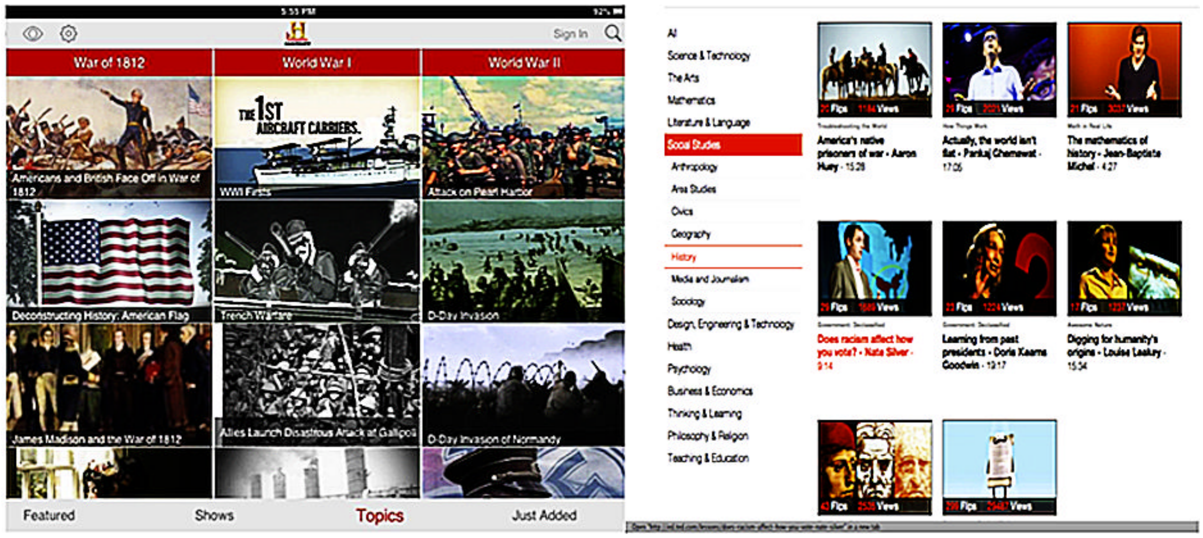
In this one-to-one networked environment, Michael found that his role shifted to that of information dispenser to a curator of web content. Instead of simply providing historical facts to his students, Michael pointed his students to appropriate online resources, allowing them to learn about a topic in a more personalized way. The *History Channel* app (see Figure 3), for example, provides students with short 3-5 minute video clips on many topics in both American and World history. Michael frequently asked students to view those clips for homework or to live up a warm-up activity by giving students a break from listening to the teacher. Further, the *History Channel* app provided students with access to authentic data through interviews with historians or other experts on a topic.

Similarly, *Discovery Education* app as well as Ted Talks (see Figure 3) available through *TedEd* (http://ed.ted.com) allowed Michael to empower students with access to both information provided by experts in the field as well as formative assessments through complete inquiry-oriented online activities. Rather than discussing the Electoral College with students in class, for example, Michael created a module using the *TedEd* platform that allowed students to work on the materials at home on their own pace. The lesson not only included materials from *TedEd* talks but also included multiple choice "dig deeper" questions written by Michael to help students parse out the important information from the *TedEd* video talks. The *TedEd* platform allows teachers to "flip" their classroom by building online activities using *TedEd's* library of talks as well as videos found on portals such as Youtube.

Authoring Apps to Support Knowledge Construction and Creativity

Authoring apps such as *ShowMe* and *iMovie* have the potential to encourage student expression and creativity, promote knowledge construction, and empower students to share their own creative interpretations of learning. In Michael's class students

Figure 3.



use both apps in a variety of ways. Regarding *ShowMe*, Michael frequently asks students who are ahead of their peers and understand a concept well to record and share *ShowMe* presentations explaining the concept to their peers. This approach not only empowers the students who have mastered the materials but it also allows them to illustrate their understanding in creative ways and take on the role of teachers. Michael frequently noted that students enjoyed using *ShowMe* not only because of its interactive features but also because of its ability to provide students with a teaching role in the classroom, thereby breaking down traditional teacher-student dynamics.

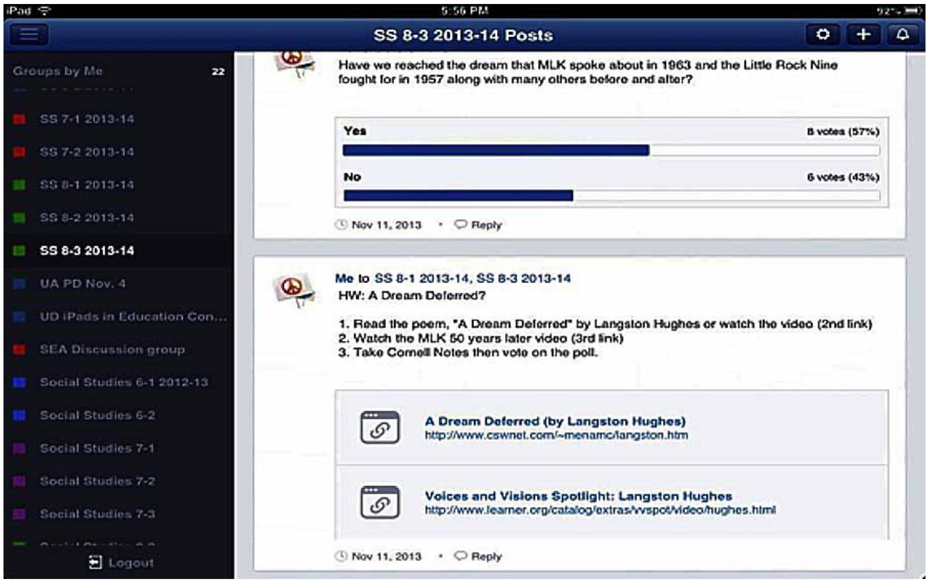
Similarly, *iMovie* app allows students to create digital stories or movies that are as close to a Hollywood production as it can get. Choosing between trailers or personalized projects options, students can create multimedia presentations complete with text, images, audio, video, background music, transitions and other interactive features. The most popular use for *iMovie* in Michael's classroom is for student-created presentations. Students enjoy being the producer, director and writer of their presentations while Michael appreciates the versatile nature of the app, which could be applied on any social studies topic. Besides demonstrating their learning and understanding of a topic, use of *iMovie* enables students to cultivate higher-order thinking skills by focusing on the main points and important features of the topic at hand and the ways in which multimedia can be used to support the delivery of the main idea.

Mobile Apps to Support Communication, Collaboration, and Social Interaction

One of the most widely touted benefits of mobile learning is in its ability to support communication, collaboration and social interaction. There are currently a number of apps that support these processes. In fact, such apps capitalize on human-centered views of mobile learning because they highlight the affordances of mobile devices to support interactions with peers in a variety of settings. In this section we focus on two apps used in Michael's classroom namely *Edmodo* and *Voicethread*.

Edmodo bills itself as the place "where learning happens." A safe social networking site for teachers and students, "Edmodo helps connect all learn-

Figure 4.



ers to the people and resources needed to reach their full potential." A key feature of *Edmodo* is its Facebook look-alike interface. Michael chose *Edmodo* particularly because of its Facebook look-alike interface which gave it added buy-in value for his middle school students who are typically either begging parents for Facebook accounts or are in their infancy using such platforms (see Figure 4). As one student in Michael's class put it, "it's like Facebook for Education". By bringing *Edmodo* into the classroom Michael takes steps into his students' world while still controlling who they can friend.

Michael's use of *Edmodo* in the classroom takes many forms including its use as a social network, a learning and content management system, and an assessment portal (see Figure 4). Michael routinely uses *Edmodo* to engage students with warm-up exercises polls and quizzes. Further, *Edmodo* serves as a classroom portal where *ShowMe* presentations and other materials are shared with the classroom community. By embedding the links directly into *Edmodo*, Michael turns it into a one-stop shop for his students – a place where they can access materials, ask questions, give and receive feedback and share their work with their peers and the teacher. While initially Michael found that students tend to respond to his own postings, as they grow more familiar with the app, they begin posting on their own. Further, students' postings reveal that they are careful of what they say online and how they say it. As a result, *Edmodo* not only gives students a voice within and outside the classroom but it also teaches them digital citizenship skills in an engaging and interactive way within a safe social network site.

While *Edmodo* is used to support collaboration and social interaction, *Voicethread* app is primarily used to support "conversations on the cloud." Simply put, teachers and students can use *Voicethread* to have conversations about a topic that is stored within *Voicethread* and is accessible both online and using the *Voicethread* app on the iPad. The *VoiceThread* creation tool allows users to upload many types of files including PDFs, Powerpoint/Keynote slideshows, pictures and video from both the website and from the app. Once uploaded, *VoiceThread* allows users to narrate any of the above media types and push them out to an audience through a unique link.

The materials can be publicly accessible or can be restricted to students within a class. Subsequently, students can comment on the materials using text, audio or voice comments, thereby allowing for rich discussions to take place both inside and outside of the classroom around the clock. Michael used the *Voicethread* app extensively in his class to support conversations on the cloud or "connect all of our iPads together" as one student put it.

During the unit on the Civil Rights Movement, for example, Michael aimed at helping students learn about the movement's origins, its evolution in the 1960s, and the court cases that shaped the book students were reading as a class, called *Warriors Don't Cry*. The particular book depicted the Little Rock Nine's struggle to integrate Central High School of Little Rock, Arkansas. Previously done through a classroom lecture over a 45-minute classroom period, Michael decided to use *Voicethread* in conjunction with a flipped classroom approach to expose students to the materials in a more engaging way. Initially, Michael uploaded a PowerPoint presentation he had created as the basis for his lecture notes and ordered the slides so they would appear in his preferred order. After the initial set up, Michael narrated the presentation in *Voicethread*. By using the sharing feature of *Voicethread*, Michael generated a unique link, which he posted within *Edmodo* along with a set of instructions for students. Embedded within *Voicethread* were specific question prompts that asked students to record their own ideas on the materials at hand. According to Michael, students' comments were fascinating; often making connections to the relevant portions of the memoir they were reading, asking questions and answering other students' questions. By using *Voicethread*, Michael took a one-way lecture presentation and turned it into a rich, interactive discussion. By flipping the classroom using *Voicethread*, students were able to review the materials at their own pace, pause, rewind and fast forward threads and even use the doodling tools available in *Voicethread* to draw and point out features on the screen while recording their comments.

In addition to using *Voicethread* in conjunction with a flipped classroom approach, Michael also used *Voicethread* to facilitate collaboration across classrooms. During the year, Michael's students hosted a group of third graders from the school who wanted to attend a class debate, as they too were learning the skills of debate. Following that face-to-face visit, the third grade teacher wanted to host the seventh graders to attend the third grade debate. Scheduling conflicts, however, rendered it impossible for the seventh graders to attend the debate. As a result, the third grade teacher taped the students' debate, which was subsequently uploaded into *Voicethread* and posted as a web link within *Edmodo*. Students accessed *Voicethread* on their iPads and provided feedback to the third graders' debate using the commenting features available in *Voicethread*. As a result, *VoiceThread* not only allowed the third and seventh grade classes to "meet" a second time but it also enabled the younger students to hear the thoughtful comments made by seventh grade students, some of whom were their older siblings.

Use of Mobile Apps to Support Anytime Anyplace Learning

In the quantum perspective of learning, Janzen, Perry & Edwards (2012), assert that learning is multi-dimensional and occurs in various places simultaneously. Yet, many classrooms continue to look the same, often banning mobile devices such as smartphones that allow students to break down school with out of school barriers. The use of iPads enabled students in Michael's class to work in multiple places both within and outside classroom walls. On many occasions Michael observed students working on classroom materials in the hallways, at a meeting table between classrooms or in the vestibule to allow for a quieter space. Students welcomed this independence to not only complete their coursework but to do so on their own terms in ways in which they chose. Students also reported using their iPads while mobile – such as checking their homework before dismissal and then logging again on the homework portal upon arrival at home. Others spoke about using their iPads in the car, bus or before and after sports events to read materials using the *Kindle* app or *iBooks* while on the go.

More importantly, use of iPads created a multiplicity of physical and virtual space where students accessed instructional materials and completed schoolwork. Students, for example, noted how they used their iPads at school to take notes, write their homework, and later access these materials at home while completing homework. At the same time they reported being relaxed about it because even if they forgot to write things down, the virtual space available through the *iHomework* app allows them to log on and check their homework. Further, the availability of various social media features allows them to ask other peers questions and clarifications virtually.

DISCUSSION AND FUTURE RESEARCH DIRECTIONS

In this chapter we provided examples illustrating the ways in which use of tablets and mobile apps can support individualized instruction, the development of 21st century skills, and anytime anyplace learning. More importantly, these examples illustrate a model for mobile learning which utilizes mobile devices to support "conversations across multiple contexts amongst people and personal interactive technologies" (Sharples et al., 2007, p.224). Obviously, the examples we provided are limited in scope as they only provide a portrait of one social studies teacher in a privileged and supportive school setting. Nevertheless, they illustrate the ways in which practitioners like Michael who are willing to take risks can utilize mobile devices to support new models of teaching and learning advocated in the mobile learning literature. As similar initiatives are growing around the country and the world, it is critical that we understand more about the ways in which teachers across content areas are adopting and adapting mobile devices for learning in a variety of settings, particularly in light of what we know about how people learn.

In fact, as with previous forms of technology, the success of tablets and mobile apps largely depends on teachers' abilities to create learning experiences that capitalize on the affordances of these tools. In a recent review of 112 apps, for example, Murray and Olcese (2011) found few examples of iPad applications that support truly innovative teaching and learning. Rather, many apps represented materials similar to digital flashcards, focusing on quizzes and recall of factual information rather than the development of 21st century skills. During the course of this study and extensive research and experimentation with new apps, Michael and his colleagues realized first hand the important role of teachers in selecting apps that can support the learning experiences of their students. Despite reviewing numerous "essential apps for educators" and "best apps for teaching" recommended in the practitioner literature, Michael noted the importance of first hand experience in looking at the capabilities and functions of apps in relation to his students' needs, his pedagogy and his curriculum.

The above findings squarely emphasize the important role of teachers in selecting apps and orchestrating learning experiences that help students evaluate and synthesize information, share and report back through personal and collaborative spaces, pursue their own interests, and become creators of new media. As a result, to help teachers accomplish these goals, it is important that schools continue to offer professional development experiences as well as support mechanisms that facilitate the transition to mobile learning. At Michael's school, teachers met once a week to share implementation ideas and experiences as well as give and receive support on how to use and identify apps. Similar support efforts were also utilized at the student level through a weekly morning meeting where students learned how to navigate commonly used apps in school and received face-to-face and online support from a "tech-squad" peer group. Further, the school provided on-site technological support through a full time staff member, created acceptable-use policies, highlighted safe and responsible use of mobile devices, and communicated regularly with parents to establish clear guidelines on iPad use at school and at home. These activities required careful planning and collaboration among teachers, administrators, parents and students. We recommend that researchers, administrators and practitioners interested in the implementation of mobile initiatives consider these issues ahead of time. At the same time we hope that the examples provided in this chapter serve as a guide to practitioners interested in leveraging the unique capabilities of tablets and mobile apps to create learning environments that are responsive to the needs of the Net Generation.

CONCLUSION

In the opening segment of this chapter we described the case of Andrew, a middle school student using an iPad and a selection of mobile apps to engage in a warm-up social studies activity. The activity provided a glimpse of how mobile devices allow students to access information instantaneously both at school and at home, make meaning of the information gathered, communicate ideas in a virtual space, and gain access to an online community of peers. The case of Andrew and the subsequent examples provided in this chapter highlighted the ways in which use of tablets and mobile apps can signal a pedagogical shift in classroom practice in order to support individualized instruction, the development of 21^{st} century skills, and anytime anyplace learning.

KEY TERMS AND DEFINITIONS

21st Century Skills: 21st Century skills include the ability to access and evaluate information, create and innovate, communicate in new ways, and collaborate effectively.

Anytime Anyplace Learning: Ability to access educational materials independent of physical and time constraints.

Educational Application (App): A software program that runs on a mobile device.

Flipped Classroom: A blended classroom model in which what is typically done in class and what is typically done as homework is inverted or flipped using technology.

Individualized Learning: A method of instruction in which educational materials are tailored to the needs and interests of individual students.

Mobile Learning: Learning where the dominant technologies used are mobile devises.

Smartphone: A mobile phone with computing capabilities.

Chapter 24
Increasing Research Students' Engagement through Virtual Communities

Maria Limniou
University of Liverpool, UK

Clare Holdcroft
Manchester Metropolitan University, UK

Paul S. Holmes
Manchester Metropolitan University, UK

ABSTRACT

This chapter describes important issues regarding research students' participation in a virtual community. Within a virtual community, university staff can communicate with research students without geographical/space constraints, and research students can exchange views, materials, and experience with their peers and/or academics in a flexible learning environment. Students' participation in virtual communities is mainly based on socio-emotional and informational motivations. Initially, this chapter describes the conditions of research in a traditional environment and the role of students and academics in it, along with the role of pedagogical and psychological aspects in virtual communities. Examples from a university virtual community developed in a Virtual Learning Environment and a Facebook™ closed group are presented. Apart from discussion forums, blended learning activities also increase students' engagement in virtual communities. Technical issues and difficulties based on different learning environments and university members' experience and familiarity with technology are highlighted and discussed.

INTRODUCTION

The word *research* can take on a variety of different meanings. For many students and academic staff, the term can have different implications depending on their research discipline. The term research evokes a number of connotations: the reading and gathering of information from books, journals, or other printed resources; the undertaking of experiments in a laboratory environment;

DOI: 10.4018/978-1-4666-8246-7.ch024

and the analysis, collection and interpretation of data. Research encompasses all of the above as a process of systematic investigation with the objective of creating new knowledge. According to the Research Excellence Framework (2011; p. 48), research "is defined as a process of investigation leading to new insights, effectively shared," which may include a definite set of procedures and steps, such as problem identification, data gathering and interpretation, action on evidence and result evaluation. The majority of researchers work independently in one or more of the traditional environments, gathering, interpreting and evaluating experimental data in order to complete their research project to create new knowledge. The interaction between students and academics (supervisors) is mainly based on a face-to-face communication. The frequency of communication is dependent, in part, on students' and academics' workload, styles, and requirements in relation to the disciplinary practice. For example, in a Science and Engineering faculty, students and academics may have multiple and frequent informal interactions since research projects may be conducted in laboratory settings, which may require close supervision of specialist techniques. In a Humanities and Social Science faculty, however, student-academic interactions may be less regular and communication usually takes place in formal meetings (Heath, 2002). Research students, during their studies, may also interact with other academics, such as librarians and technicians, in addition to their supervisory team. By developing contacts and interacting with other staff and students, a research student may save time involved in independent research. University personnel who are experts in a scientific topic or a field are often willing to provide research students with relevant information but, in most cases information holders do not meet with the research students who are in need of the information. Part-time research students are faced with their own unique situations, and are often struggling to balance careers and personal responsibilities alongside their research. Thus, they may not visit the University as frequently to develop their contacts and to determine who is an appropriate expert (academic or not) to assist them (Watts, 2008).

Moreover, although research students need to follow a specific research model that is different for each discipline, they should develop and use a range of transferable skills to achieve their aims, such as careful planning, observation, evaluation and critical reflection, along with presentation and publication skills. For that purpose, the UK organization Vitae, which supports the personal, professional and career development of researchers, has designed a Researcher Development Framework by providing guidance to research students and staff to develop knowledge and skills (Vitae, 2013). The Framework is informed by consultation within academia and industry, and identifies the characteristics that typify an excellent researcher. These characteristics are clustered within four domains:

- Knowledge and intellectual abilities;
- Personal effectiveness;
- Research governance and organization; and
- Engagement, influence and impact.

The aim of the Framework is to encourage "researchers to plan their personal and career development through achievable goals within an action plan; identifying their strengths and developing those areas deemed weaker or important to their career progression to enable them to realize their potential" (Vitae, 2013). Most UK universities have engaged with the principles of the Researcher Development Framework and have organized and delivered workshops in order to assist their research students to obtain the necessary skills.

In a traditional research environment, research students typically learn to conduct research by working closely with their faculty, following a specific research model well supported by their supervisory team; and they often attend face-to-face workshops in order to develop skills and attitudes valuable for their research project. According to Protivnak and Foss (2009), collaboration between students and faculty members is an important factor for successful completion of research studies; and the relationships between students and university staff and the attendance of events and workshops enhance the sense of belonging to a research community. Generally, any group of people who share a physical location, and/or share a common interest or characteristic such as research, belong to a community (Blanchard, 2004). However, according to a recent Postgraduate Research Experience Survey in the UK for research studies, only 54% of respondents expressed that they felt integrated within the Department's research community and 65% considered that their department provided limited opportunities for sharing "campus space" with others and opportunities for interactions with the University staff (supervisors, other academic staff, non-academic staff) and with their peers (Hodsdon & Buckley, 2011). Therefore, it seems that the social ties of a research community are not strong enough, as researchers feel isolated inside the traditional research environment and research students seldom interact with their peers or with University staff. Moreover, they do not seem to have strong relationships before, during, or after their participation in face-to-face workshops with their peers and the workshop tutors. According to Ali (2006), the independent nature of undertaking research and the feelings of isolation have often been associated with higher levels of non-completion.

In order to enhance the sense of belonging to a community, Universities have adopted other modes of communication supported by the extent of technology mediation of interaction (computer-mediated communication). Specifically, the development of the Internet and the World Wide Web (WWW or the Web) gave to the world several advantages over the communication media, including interactivity, user-involvement, time-independence and worldwide access. Through the first-generation of web technologies (Web 1.0), a web server could only deliver information to users. However, the second generation of Web technologies (Web 2.0) supports two-way communication, as users can create and easily upload new information to the Web server. Therefore, the users are not only information consumers, but also information contributors. Web 2.0 technologies allow users to collaborate with others, to share ideas and documents, to create online collaborative documents and to socialize with others (Collis & Moonen, 2008). Collaborative wikis, blogs, photo and slide sharing, and online social networks are used by millions of people in everyday life either for personal/social or professional/organizational purposes (Ponte & Simon, 2011; Shang, Li, Wu & Hou, 2011). These collaborative platforms have many common features, such as content creation and sharing (images, files), provision for discussions related to the content (comments, online posts and forums), user-to-user connections (private messaging) and networks of users based on common interests (Kolbitsch & Maurer, 2006). An example of an online social networking platform is Facebook™, that launched in 2004; it enables users to keep in touch with their (old) friends, classmates, relatives and new friends, whilst sharing resources such as photos, videos and news. Facebook™ also provides layers of common identities via groups that are designed to connect users with a common interest. That specific "group function" of Facebook™ can support and facilitate virtual communities. Overall, Web 2.0 technologies give users the opportunity to engage virtually with a group of people with common interests in order to perform activities in a common cyberspace such as the sharing of ideas, photos, documents and online chat (Beye, Jeckmans, Erkin, Hartel, Lagendijk & Tang, 2010). Any group of people who may or may not meet one another face-to-face, but who have similar interests and try to achieve similar goals by exchanging ideas, views, documents, experience, etc. through online web networks belong to a virtual community (De Moor & Weigand, 2007). Usually, a virtual community-based approach facilitates informal sharing of knowledge available from experienced and skilled people and virtual communities are characterized as unique, addressing issues such as communities of practice, virtual collaboration and knowledge management with different ways, depending on people, shared purposes, policies, and computer systems (Koh & Kim, 2004). The four characteristics (Lee, Vogel & Limayem, 2002) that define a "virtual community are:

- A virtual community is built on a computer-mediated space (cyberspace);
- Activities in the virtual community are enabled by Information and Communication Technology;
- The contents or topics of the virtual community are driven by its participants; and
- The virtual community relationship evolves through communication among members." (p. 2)

However, it is a challenge for people who develop and/or facilitate a virtual community to build a commitment from all the members, as even the most successful online communities fail to engage all the members and to encourage active participation in it. For example, in Wikipedia, 60% of the users never return the benefits that they gain from the community (Panciera, Halfaker & Terveen, 2009). Some members in a virtual community feel greater commitment and they provide content, enforce norms of appropriate behavior, and perform behind-the-scenes work to keep the community going (Farzan, Dabbish, Kraut & Postmes, 2011).

The aim of this chapter is to review important issues regarding the research students' participation in a virtual community. The authors have chosen to provide different examples from a virtual research community under the perspectives of building up a new one. The role of technological resources, the student-teacher interaction, the role of communication, and the enhancement of the sense of community among the University members through the interactions between academic, students and non-academic staff are discussed.

BACKGROUND THEORY

Students who were born after 1980 belong to the Net Generation and have a fundamentally different way of processing information and ways of communicating compared to generations before. These students feel comfortable with technology and the way that they learn is task-oriented and experiential. Thus, they prefer to receive information quickly and use multiple/multi-modal communication channels to access information and to e-communicate with friends, peers, and teachers (Oblinger & Oblinger, 2005). Many universities have adopted Information and Communication Technology (ICT)-enhanced environments in order to support the teaching that they offer. Virtual Learning Environments (VLEs), such as WebCT©, BlackBoard® and Moodle™ ©, give University staff the opportunity to deliver online courses or to create virtual communities (Blas & Serrano-Fernández, 2009; Limniou, Papadopoulos & Kozaris., 2009; Ngai, Poon & Chan, 2007). VLE systems support teaching and learning by offering tools which enable teachers to embed audios, videos, animations, PowerPoint presentations and/or simulations to the taught courses. In addition VLE systems allow teachers to interact synchronously and/or asynchronously with their students through collaboration tools such as chat rooms and/or discussion boards. Management tools, such as the selective release of the learning material, the students groups' creation and the tracking of students who participate in Virtual Space, offer academic staff extra possibilities to supervise their courses and engage students in teaching and learning. From a pedagogical point of view, by integrating VLEs into the teaching approach, academic staff can engage students in the process of learning through discussions, individual feedback based on students' actions and/or performance and their awareness of their knowledge and areas of weaknesses. Learning activities through discussion boards allow students to exchange views on difficult topics and allow academic staff to create a flexible teaching approach enhancing their communication with their students. Additionally, students can be connected to a community at anytime, anywhere, without being time- or place-constrained (Limniou, 2012). By integrating the technological developments into courses/workshops teachers have the opportunity to design different teaching strategies (Limniou & Papadopoulos, 2011). Generally, the combination of pedagogical approaches, such as behaviorism, socio-constructivism, and cognitivism, with or without instructional technology, can produce an optimal learning outcome (blended learning) (Bliuc, Goodyear & Ellis, 2007; Driscoll, 2002).

Pedagogical and Psychological Aspects Related to Research Studies

Behaviorism is based on the assumption that teachers are able to transfer knowledge to students' minds. Specifically, this model defines learning as a change in observable behaviors due to environmental stimuli, where learners are essentially regarded as passive and shape their behavior through positive or negative reinforcement and punishment (Slavin, 2006). This style promotes a clientele or patronage type of supervision, where supervisors act more as "sage on the stage" rather than a facilitator of learning and research. Thus, the feedback that the supervision team provides to research students is based on the concept of rewards and reinforcements, which are more focused on the technical aspects of the research and the thesis production rather than on how the students are shaped (Zuber-Skerritt & Roche, 2004). However, the supervised student should have the opportunity to receive not only information on correct formats of presenting a thesis, but also information on what to research, how to argue and arrive at the conclusions, and how to develop critical thinking skills (Deuchar, 2008).

We argue that pedagogical theories other than behaviorism might be more suitable to better assist academics to help their students to process and obtain knowledge and skills. For example, constructivism provides an account of how individual learners obtain knowledge through their interaction with the world. Constructivism advocates that learners learn better when given the opportunity to actively process their own knowledge through feedback by working in a more student-centered learning environment. The constructivism model comprises "cognitive constructivism" and "socio-cultural constructivism". According to cognitive learning theories, the amount of supervision depends both on how academics present materials to students and on how the student processes the material (Quan-Baffour & Vambe, 2008). However, it seems that cognitive learning theories, in the cases of supervision and research, cannot fill the gap, which is coming from the social interactions and stressful situations (Mearns, 2009). In a socio-constructivism approach, learners share experiences and one helps the other to learn, so knowledge is essentially developed through social interactions. Collaborative Learning, which is a framework of constructivism, involves the mutual engagement of learners in a coordinated effort to solve a problem or to examine an issue all together. Thus, through the socio-constructivism process, teachers should treat students as learners capable of critically questioning dominant beliefs and mainly the teacher should focus on students' empowerment (Schulze, 2012). According to Biggs (1999), teaching and learning activities based on constructivism can be categorized as teacher-directed (e.g. by ensuring that a presentation is clear), peer-directed, and/or self-directed. Features for peer-directed teaching are:

- "Learning takes place in an active mode;
- The teacher is more a facilitator than "sage on the stage";
- Teaching and learning are shared experiences between teacher and student;
- Students participate in small-group activities;
- Students must take responsibility for learning;
- Discussing and articulating one's ideas enhances the ability to reflect on one's own assumptions and thought processes;
- Students develop social and team skills through the give-and-take of consensus-building; and
- Students experience diversity, which is essential in multicultural democracy". (Kirschner, 2001, pp. 4-5)

Community and Social Learning

Community-based learning is founded on socio-cultural and constructivist learning theories and is focused on the concept of communities such as communities of practice, communities of interest, learning communities and knowledge-building communities (Fischer, Rohde & Wulf, 2007). A community of practice has been defined as a "network of people who share a common interest in a specific area of knowledge and are willing to work and learn together over a period of time to develop and share knowledge" (Sobrero & Craycraft, 2008). A member of a community can act as a knowledge provider to others who act as knowledge recipients. (Kim, Song, and Jones, 2011). Knowledge could be transferred directly by communication between individuals or indirectly from a knowledge archive. Specifically, the way that the members of a community acquire knowledge and information can be through reading, sharing, observing, and experiencing. In addition community members should invest the optimal effort and time in order to obtain the specialized knowledge related to their task and/or performance. According to social cognitive theories, there are natural tendencies of individuals to alter personal behaviors based on the observed behavior of others. Learners' behavior is determined by the continuous, reciprocal interaction among behavioral, cognitive, and environmental factors (Bandura, 1986). Specifically, learners play a proactive role in a behavioral adaptation, rather than simply undergoing experiences in which environmental stressors act on their personal vulnerabilities (Bandura, 2001). The three models for learning through observation identified by Bandura are:

- A live model, which involves an actual individual demonstrating or acting out a behavior;
- A verbal instructional model, which involves descriptions and explanations of a behavior; and
- A symbolic model, which involves real or fictional characters displaying behaviors in books, films, television programs, or online media.

Following Bandura's model (2001), the four key elements, which play a significant role in whether social learning is successful or not, are:

- **Attention:** Anything that distracts learners' attention has negative effects on observational learning including distinctiveness, complexity, functional values and one's characteristics such as sensory capacities, perceptual set and past reinforcement;
- **Retention:** The ability to store information and to recall it later that includes symbolic coding, mental images, cognitive organization, symbolic rehearsal, motor rehearsal;
- **Reproduction:** When learners pay attention and retain the information, then they will perform the behavior that they observed, including physical capabilities and self-observation of reproduction; and

- **Motivation:** When learners have a good reason to imitate, including motives such as traditional behaviorism, imagined incentives, seeing, and recalling the reinforced model. Bandura (1995) identified the significant role that the internal reinforcements play in learning along with external reinforcement.

Virtual Community and Social Learning

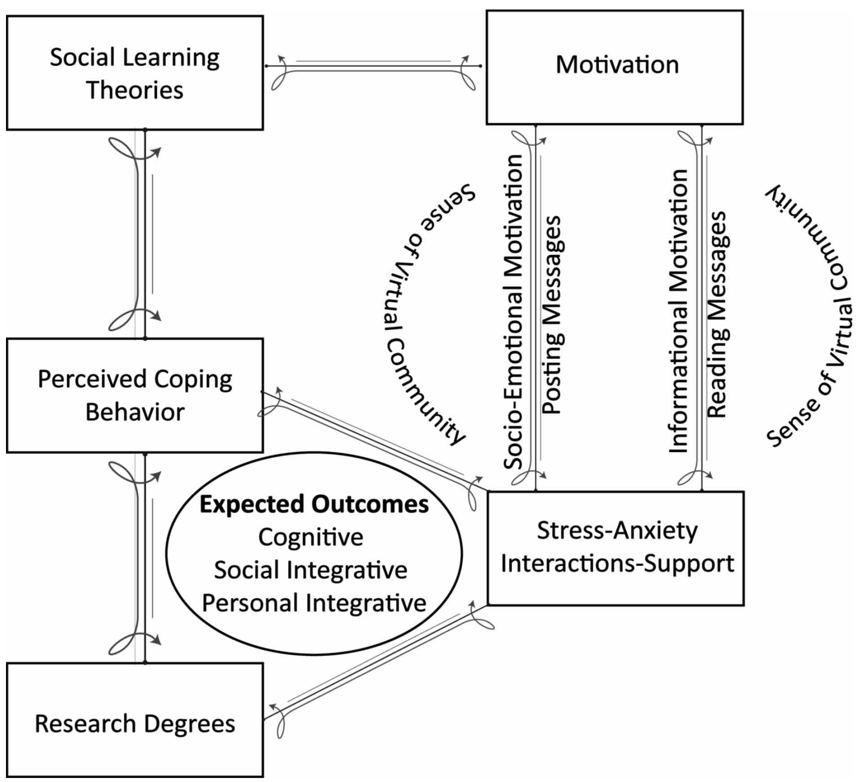
Bandura has identified the outcome expectation and the self-efficacy as the major cognitive forces guiding behavior. For example, if individuals are not confident in their ability to share knowledge, then they are unlikely to perform the expected behavior, especially when knowledge sharing is voluntary (Bandura, 1982). In the case of virtual communities, the previous two cognitive forces, along with the key element of motivation, influence the members' behavior. Specifically, members of virtual communities differ from common Internet users, as these members are brought together by shared interests, goals, needs, or practices; therefore, the barriers of complex knowledge sharing process and extrinsic reward are overcome (Chiu, Hsu & Wang, 2006). Thus, their motivation in learning through Computer-Mediated Communication (CMC) is influenced by the flexible learning environments, learning resources, and active participation in the learning process. Technology can enable and facilitate the communication and transmission of information to the students by providing them with the opportunity to exchange knowledge and resources and to develop mutual understandings. Authentic learning resources can bring reality into the learning environment assisting the students to prepare themselves for real-life situations (Limniou et al., 2009). Additionally, a member's decision in a virtual community to either read or post messages is dependent on whether (s) he believes the benefits of such action outweigh the costs (Ren & Kraut, 2009).

Online support behaviors are associated with a greater Sense of Virtual Community and social connectivity that is related to the reduction of stress (McKenna & Green, 2002). Specifically, informational and socio-emotional support play a significant role for members of a community and are directly related to the motivations that users have in order to actively participate in a virtual community. Socio-emotional motivation refers to comfort, relationship with others, and/or other relationship benefits from online interactions, whilst informational motivation refers to advice, suggestions, and/or recommendations (Welbourne, Blanchard & Wadsworth, 2013). Overall, the Sense of Virtual Community reflects the feeling that individual members have of belonging to an online social group where the members will gain valuable knowledge and improve learning opportunities (cognitive expectations). Although members of virtual community have common interests in the content and the motivation for activity, negative rumors or messages are not easily replaced with positive messages, information, or rewards (Silius, Miilumaki, Huhtamaki, Tebest, Merilainen & Pohjolainen, 2010). Figure 1 illustrates a schematic virtual community Model of Research presenting a connection between social learning theories along with motivations. Through this model, research students could perceive a specific behavior or obtain skills under stressful situations or through interaction with others.

MAIN EMPHASIS OF THE CHAPTER

By following the above model, the authors will describe how a virtual community can be built up based on members' characteristics, technology choices, and University facilities. Additionally, they will provide examples from online discussions, identifying the benefits and the difficulties for the members.

Figure 1. Schematic of the virtual community model



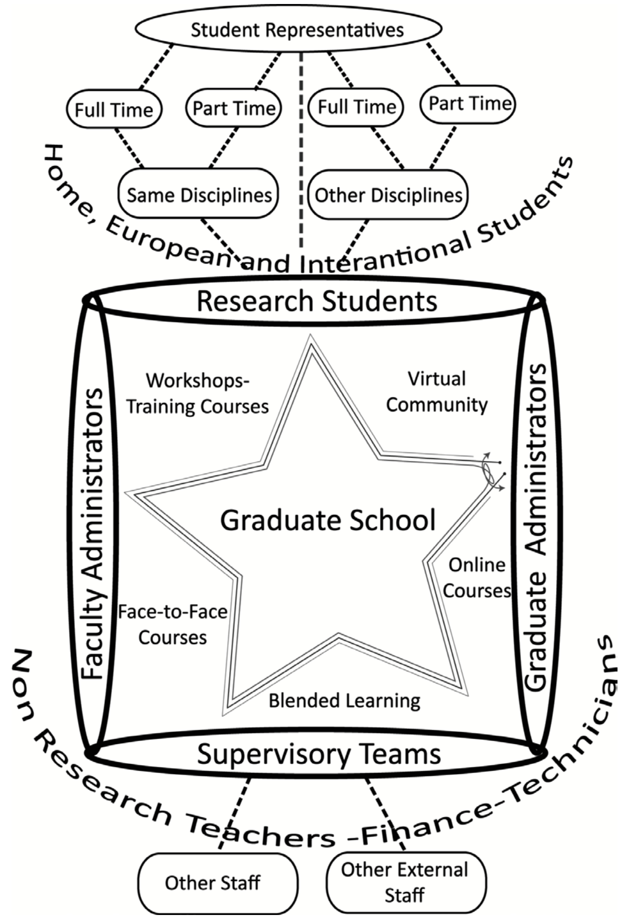
Members' Characteristics

In order to build up a virtual community for Research, we should study the potential members' background, experience and needs. In our case the potential members are university research students and staff. As in any United Kingdom University, Manchester Metropolitan University (MMU) has home (UK), European Union (EU) and overseas students who can follow a part- or full-time research degree course through either face-to-face or distance learning. In all cases, research students work closely with an appointed supervisory team that assists them to formulate their research topic and ensure that students are making progress towards completing the research on time. In each faculty, there are research administrators who provide advice and support to academics, students and applicants and help to organize events such as research symposiums/events for all the research staff and students. The Graduate School manages, monitors, and evaluates the research degrees across the University. It collaborates with research administrators, staff (internal and external), other offices/units that facilitate students' progress, enrolment, admissions, etc. and it is in a close collaboration with research students who are the key stakeholders. Additionally, during their studies, research students have access to a wide range of personal advisers, guidance, and support, including financial and careers advice, disability and counseling support. For example, librarians, technicians, and the international office all need to be in collaboration with the Graduate School in order to ensure that they provide focused and dedicated support to postgraduate research students.

One difficulty that MMU research students usually face in their research projects is the lack of communication between themselves and university staff. In addition, research students need to develop transferable skills such as time management, managing a research project, etc. during their studies. The social interactions between research students and University staff can be enhanced through virtual communities where, through virtual discussions (synchronous and/or asynchronous), research students could discuss issues related to their research with their peers and university research staff such as progression enquiries and research methodologies. In addition, students can find related documents, learning material, and useful external web links related to the research environment. Students could get information and feedback not only from their supervisory teams, but also from other non-academic staff, such as librarians, technicians, research administrators and their peers.

In order to assist research students to develop academic and vocational skills and lead on the governance of postgraduate research degrees in the University, the Graduate School delivers workshops following the Vitae's Researcher Development Framework. The student development program has been created to ensure that postgraduate research students gain transferable skills in addition to all the skills required to successfully manage their research. Some of the workshops that are offered to research students are related to the management of a research project, networking skills, thesis and publication formatting, Cite Rite™ with EndNote™, presentation skills, and qualitative and quantitative research methods. Due to the fact that by following the traditional way of teaching little motivation is given to students in order to solve problems or to collaborate with their peers during the workshop. Vitae recommends the adoption of blended learning activities in order to engage students in the learning process (Vitae, 2013). In this way, students' motivation is enhanced, allowing teachers to meet students' needs. The activities could support either face-to-face and/or online modes. Figure 2 illustrates the role of the MMU Graduate School in Research.

Figure 2. Schematic model for the role of the graduate school in research



Developing a Virtual Community

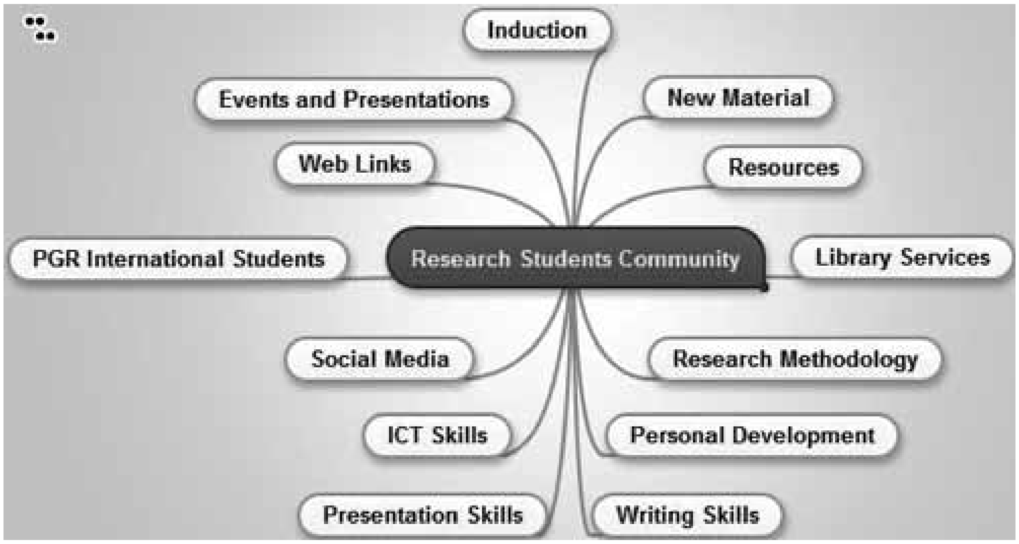
In order to build up a virtual community, key issues such as users' familiarity with ICT, University facilities and technological developments should be taken into account. MMU has recently adopted Moodle™ as a Virtual Learning Environment, and the university policy is that all courses/workshops should have a relevant virtual space. Thus, it is compulsory for university staff to embed Moodle™ into university activities. In each faculty, there is at least one assigned e-learning technologist in order to support teachers to use VLEs and other technologies in their teaching and to verify their content quality. Other Universities often provide similar e-learning support (Limniou & Smith, 2010). Overall, the majority of the university staff has some level of support on the use of VLEs in their teaching. The reasons that Universities follow the above strategy, i.e. to support the teaching staff via e-learning technologists, is because of university staff's lack of familiarity with the use of ICT, their individual workloads, the limitations of the technology in relation to particular tasks, the different way of communications (electronic medium communication vs face-to-face), the limited training, and the lack of a reliable infrastructure (Heaton-Shrestha, Edirisingha, Burke & Linsey, 2005). Even though not all university staff are ultimately persuaded that VLEs could enhance their teaching approach, the majority of research students have previous experience on different VLE platforms and/or on social media. Specifically, regarding their familiarity with new technologies and the use of social media, 85% of research students (strongly) agreed that they have familiarity with new technologies and approximately 72% of them use social media in their everyday life. Taking into account university staff and research students' previous experiences of new educational technologies, the use of social media and the facilities and support that the University offers, the Graduate School has built up a virtual community on Moodle™ and supplements it with a closed Facebook™ group and a Twitter™ account. Some of Moodle™ 's benefits, for educational purposes, are the low cost of ownership, the high level of security, technical support, constant updates, and plug-ins. Also, the source code is available along with the ability for customization.

In the Moodle™ Research Students Community, all the members can discuss issues related to research and workshops. Students and staff with a Facebook™ account can also participate in open discussion related to research and/or to post messages, web links, files, etc. to a closed Facebook™ group through a flexible social network system. Apart from online discussions, workshops are supported by e-assignments, where research students can upload their workshop activities and the tutors can provide them with online feedback. Additionally, by creating a Twitter™ account for Postgraduate Students, the MMU research community can communicate with other intuitions, organizations, and individual Twitter™ users by disseminating information to internal or external researchers on MMU research projects and events, recruiting people for research projects, re-tweeting interesting tweets from other users, and creating a Twitter™ *#hashtag* to provide a means of grouping messages and discussions.

Structure and Promotion of Virtual Community across the University

Initially, all the university staff who participated in the virtual community were informed of the strategy of this initiative and were asked to contribute with relevant research material that they usually used in their workshops or in their supervision. Before launching the virtual community for Research to all the members, key stakeholders (such as librarians, research administrators, research staff and a few of our research students) provided feedback. One major difficulty that the developers had was to design and build a virtual Research Students Community to cover the needs and expectations of all the stakeholders. This virtual group was a heterogeneous mix of people, with mixed familiarity with educational technology and different ages, ethnicities, etc. An additional difficulty was that Moodle™ might be challenging for some users, although it provides an easy way for academics to present the materials to students, the material can be displayed on the page either as individual items or as items bundled together inside folders. As a result, the entire Moodle™ page can be quite long and course instructors need to spend some time in creating a more user-friendly learning environment. Thus, in order to make the Moodle™ virtual community more

Figure 3. A representation of the sections in the Moodle™ virtual community



user-friendly, the developers created an interactive image in which each section was illustrated. When members of the community enter the Research Students Community, an interactive image was the first item of the virtual community (Figure 3). The users could then click on the circle near to each section and be re-directed to the appropriate section quickly.

In the Induction section of the Moodle™ area, the members of the community could find information for the Induction Day, the only workshop that is compulsory for all the first year research students. Under this section, the virtual members had the opportunity to participate in discussion forums. There was general discussion forum, where all the participants of the Moodle™ space could post messages and discussion forums for specific target groups, for example, forums for faculty, forum for research administrators only, and forum only for student representatives. The Graduate School's policy was for the recently uploaded material to stay in the section entitled *New Material* for one month and then to be placed in the appropriate section. All the information and material regarding the University regulations, student handbook, student journeys, documents for Ethical approval and articles for research such as the role of supervisor, literature review for a thesis, etc. were placed under the section *Resources*. All the relevant information for the University Library (facilities, services and staff) and material for the workshops, such as Cite Right™ with EndNote™, Cited Reference Searching on the Web Science and Scopus™, which librarians delivered to research students, were under the section *Library Services*. A discussion forum was available in this section providing an opportunity for research students and staff to clarify any issues related to Library services. Under the *section Research Methodology* virtual members could find information regarding a commitment to good research conduct and the relevant workshops which were delivered by the Graduate School such as Quantitative and Qualitative Research Methods. Information about relevant workshops such as Time Management, Team Work, Manage Your Research Project and Critical, Thinking, Reading and Writing, along with group discussions and assignments for research students could be found under the section *Personal Development*. The MMU Research Students Community also contained sections on:

- Writing Skills, where information could be found for plagiarism and copyright issues along with workshop material for writing skills and writing proposals;
- Presentation Skills, where material for the workshop on how research students could improve their presentation skills;
- ICT Skills, where students could find material for specific software such as advanced Microsoft Word, SPSS, etc. along with online assignments and discussion forums; and
- Social Media, discussions and workshops for making research available to other researchers inside and outside the University, for exploring online social media and research networking platforms in order for research students to interact and communicate with other researchers developing networking skills.

Under the section *PGR International Students*, information provided by the International Office were delivered to our international research students along with an appropriate discussion forum for them. Finally, the last sections were designed in order to provide recommended external links to virtual members for further considerations/reading (Web Links) and to encourage research students' efforts to organize events and actions across the University (Events and Presentations).

In our closed Facebook™ group for researchers, virtual members could upload external web links, documents, and files related to research and invite other members to share their views on the specific digital element that they uploaded. This process was equivalent to asking for an opinion in a face-to-face meeting and it was also an ideal mechanism for promoting internal and external events to the student community. The open discussion that then took place was very useful for educational purposes, as just-in-time information was crucial in the learning process. The other use of the closed Facebook™ group was to take external links that research students and staff thought were valuable for their study and put them in the Moodle™ virtual community, as not all the members wished to be part of the Facebook™ group. In a closed Facebook™ group, anyone could see the members of the group, but only members could see posts, which provided more privacy. In addition, in order to confirm that the Facebook™ user who wanted to join our group was an MMU research student, we checked the Student Record system of the University. In the case that a Facebook™ user had a fake account, the group administrator sent him/her a personal message through Facebook™ asking for more details (his/her name and in which Faculty (s) he is studying for, etc.) to confirm his/her details with the Student Record system.

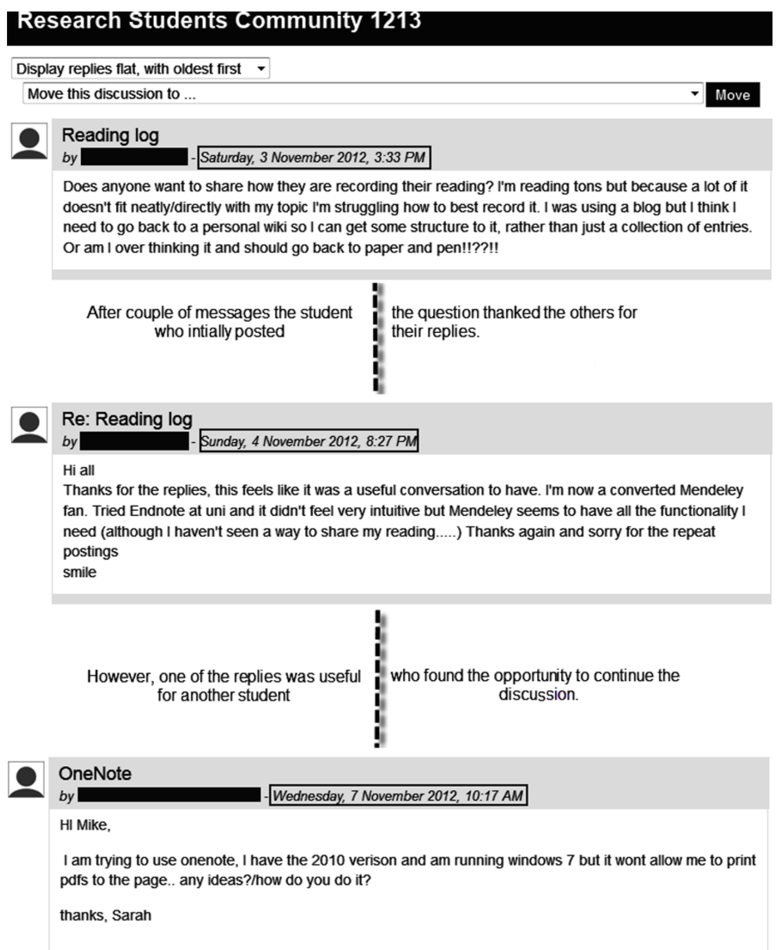
In order to promote the virtual community across the University, the capabilities of the Moodle™ space, the closed Facebook™ group, and Twitter™ account were presented to first year postgraduate students during the compulsory Induction workshop. In addition, information was circulated through printed brochures, the Graduate School website, training courses (dedicated mainly for second-, third- and fourth-year research students and university staff) and via personal contact with all the potential virtual members.

Discussions in Virtual Communities

In a comparison to a face-to-face classroom contact, virtual interactions lack the social cues such as eye contact, gesture and other expressions. This can be viewed either positively or negatively. For example, females tend to use more emotions than males in a face-to-face interaction (Wolf, 2000), which through virtual discussions, is translated through the use of emotional icons and capital letters. On the other hand, through virtual communications social pressures are reduced, as the participants feel more comfortable (Gilmore & Warren, 2007). Additionally, through asynchronous communication every research student and/

or staff member in the virtual community could potentially read and respond to other messages instantly, if these posts were relevant to their interest and/or research. Figure 4 illustrates an example from a research student who posted a message (asking for help) on a Saturday evening, and in a couple of hours other members of the community had sent other messages trying to assist her to resolve the problem. Specifically, they posted fifteen messages in less than 24 hours providing feedback to the initial question. One of the replies on the initial question recommended to the student to use EndNote. While this recommendation did not apply to the student that started the discussion it seemed to apply to another student who was trying to use EndNote but did not know how. Thus, the discussion continued based on one reply that was provided and so there were more than five messages under the same category *Reading log*. The point of this example was that, even if a research student did not start a discussion, (s)he could find the opportunity to ask other questions based on a given response. Overall, they exchanged twenty-two (22) messages on that particular question. The conclusion of the presented example is that an asynchronous discussion within virtual groups can enable multiple people to respond to a message thus increasing research students' motivation not only from an informational point of view but also from a social-emotional one as well.

Figure 4. Example for an asynchronous discussion with the Moodle™ community



We have observed that research students who were familiar with social media usually preferred to post messages via Facebook™ rather than via the Moodle™ Community. Figure 5 illustrates an example of an online discussion related to ethics. In the case of Facebook™, there were more posts than to Moodle™ Community; and as Facebook™ had the functionality of "Like", this acted as a sort of ranking system for the usefulness and/or the agreement with the specific post by other members. This capability is also present in Moodle™, in which course leaders have a tracking system, but they cannot tell if a specific post, document, resource is valuable for the members of the community. For that purpose, the Facebook™ group acted as a supplementary platform, in order to track posts and responses, and to meet the needs that the members had and what they expected from the community.

Generally, asynchronous communication allows research students to prepare their messages more carefully than in a face-to-face communication. Very often in synchronous communication, research students do not formulate their thoughts well enough through questions and answers, as they try to follow a conversation, which is relatively quick. An international research student, for example, who might struggle due to language barriers on a face-to-face discussion, by participating in an asynchronous virtual communication, might have a better chance of actively contributing in the discussion and might have a better understanding of the message by re-reading it.

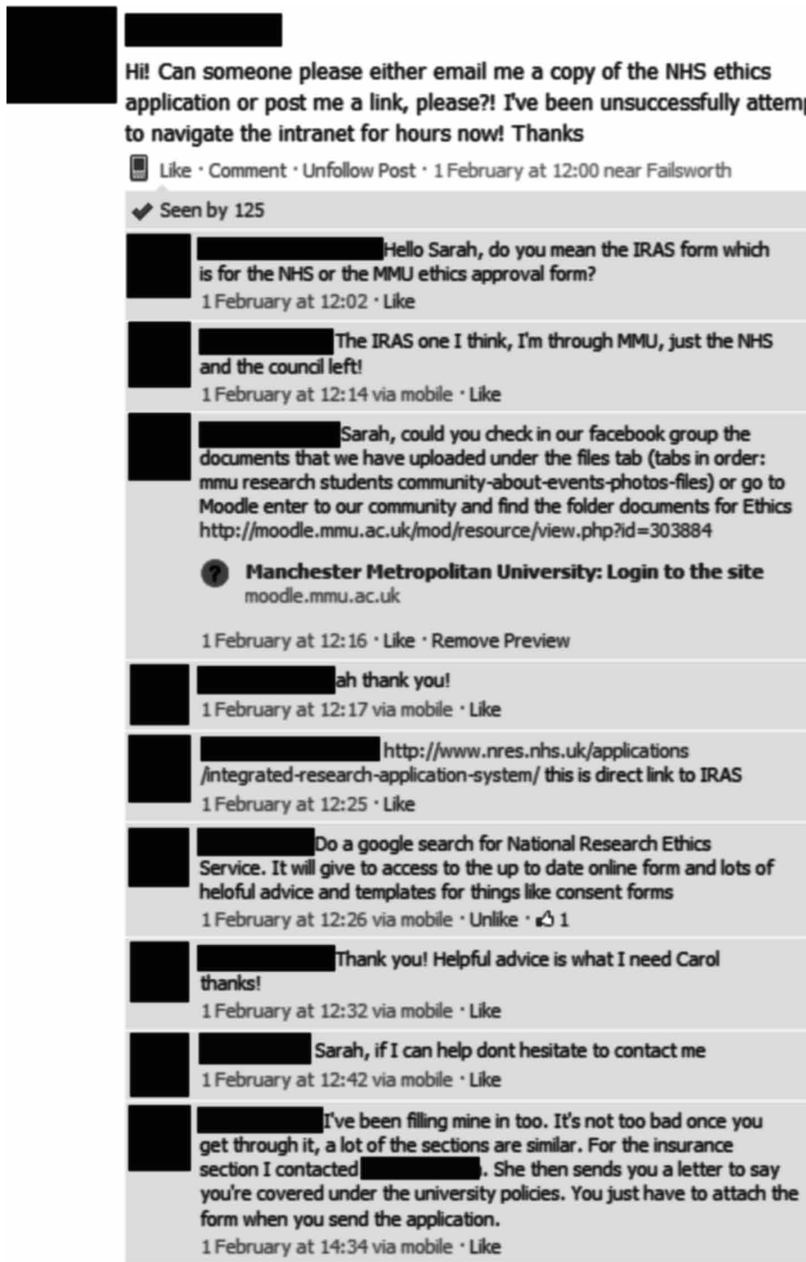
Another issue regarding the virtual community was that occasionally members complained about posts because they did not think that were relevant to their interest. On several occasions, disapproving posts discouraged other members of the community from participating in that particular discussion. For example, as briefly illustrated in Figure 6 below, a member of the Facebook™ group posted an external link that he found useful for his research. However, another member stated that (s)he found the topic and/or the discussions boring or annoying. In this particular occasion, a student replied and, in effect, isolated the negative comment, and the members continued to post messages, external files, and websites. Negative comments such as the one below might discourage students from continuing posting on the topic and, thus, a potentially constructive discussion might end prematurely.

On the other hand, in the Moodle™ community, when a member did not think that (s)he could contribute more to the discussion or did not wish to follow the discussion anymore, (s)he sent a direct message to the course leader or to the member that initially started the discussion asking to be unsubscribed from the specific discussion. These two different behaviors were mainly because of the difference between social media and Moodle™. In Facebook™ the users knew that they could put items on the Group wall, which is common practice in Facebook™, and also there was no reason to complain as it was their choice to be a member of the Facebook™ group. In the Moodle™, all research students and staff were provided with access to the Research Students Community following the University policy. They were given the opportunity to unsubscribe themselves in the case that they wished to leave a discussion. In addition, in the Moodle™ community, the members could configure their profile settings and they had three options: (a) to receive e-mails for each discussion post; (b) to receive only one e-mail at the end of the day which would include a digest of all the posts; or (c). to receive a daily e-mail per specific discussion topic.

Engagement in Virtual Community

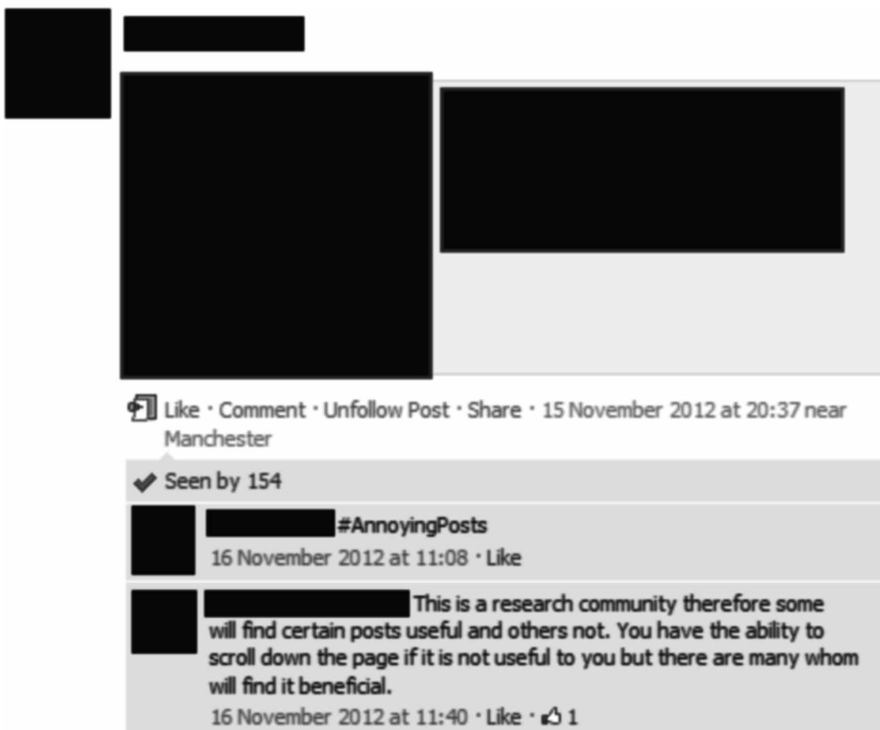
Apart from uploading e-material for the workshops through the research community, students had the opportunity to facilitate their learning process based on their learning style, characteristics, and the nature of the cognitive topic by participating in online activities and receiving feedback based on their discussion posts and/or formative assign-

Figure 5. Example for an asynchronous discussion in the virtual community's closed Facebook™ group



ments. The degree of integration of conventional (face-to-face) teaching with computer-based activities (blended learning) varied between the workshops. Figure 7 demonstrates an example of blended learning for the workshop entitled *Thesis and Publication Formatting* which combines online activities along with activities in a computer cluster. Initially, students should have read the handouts and participated in a couple of activities. Through the online discussion forum, the students received feedback by their peers/tutors based on these initial online activities. By using the online assignment tool, the research students could upload the activities before the face-to-face

Figure 6. Someone posted an external link, someone else complained and another replied



workshop. Thus, the teachers could easily discover their students' backgrounds; they could make the appropriate changes to e-material and/or change the way that they delivered their workshop. A self-paced online session, in which the research students were able to review concepts and fill the gaps between theory and practical work, built up their confidence before they entered the face-to-face session, strengthening their motivation for learning. The workshops also provided students with the opportunity to meet other research students and academic and administrative staff from across the University, thus enhancing the sense of community.

In addition, in order to increase their sense of belonging in the community, students were provided with the opportunity to be involved in teaching a part of the workshop to their peers, thus they shared their experience and skills of a specific area with their peers. This policy aimed to encourage students to actively participate in the teaching and learning process and to develop skills such as presentation and writing skills. Overall, the research students produced high quality material, had a good attitude towards being of service to the University, and had the desire to learn and share with others. By involving them in the teaching process, they remained motivated and they exhibited self-confidence. Students became engaged; and they reflected learning by real world examples through their participation, while at the same time their peers had examples from other research students who had faced similar issues and difficulties. By following this process, the workshops were conducted in a collaborative environment. In addition, the research students that participated actively in the workshops gained experience as presenters, which will be valuable for them in the future. Some of students' feedback for the workshop *Thesis and Publication Formatting* is the following:

Student 1: I thought I knew quite a lot about Word, but this course has shown me some very useful techniques that will enhance my finished thesis and making [sig.] formatting the document soooooo much easier. A very well presented and run course, that takes into account those students who work full time and have a busy young family life. I have been able, easily, to fit this around my other commitments! Very forward thinking, please please please more like this, well done!!!

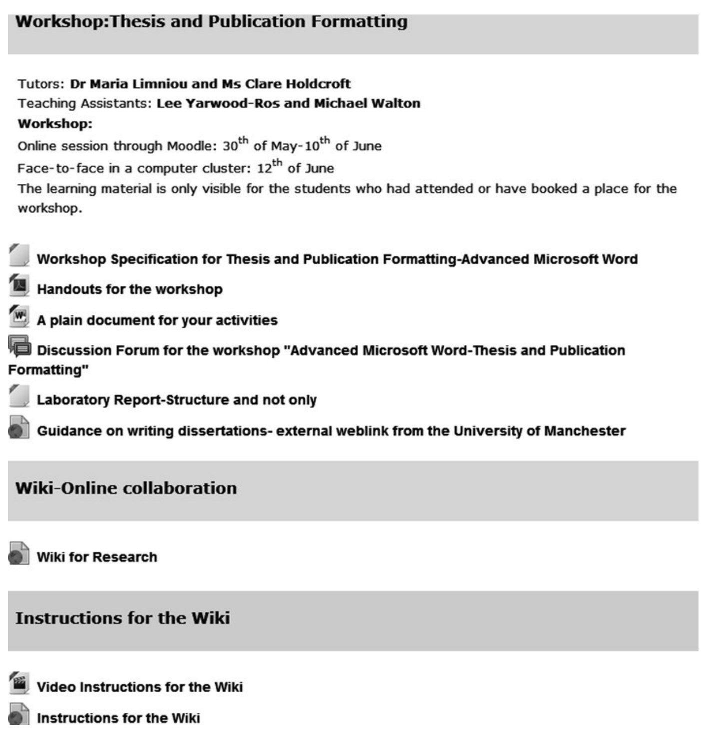
Student 2: Thank you very much you and your colleague. Really it was very interesting workshop I wish we could get some of them in near future. Personally I got lot of things I did not know it [sig.] before it really helps me to organise some of my work. Thank you once again.

Student 3: I thought workshop worked well and liked the individual and group balance. One thing I really liked was the content of the session, the Moodle™ information and the practical work. The administration of the workshop was very professional but very warm and friendly simultaneously.

Student 4: It was really useful - a whole new world of what Word can do!

One challenge that the Graduate School faced was that some of the research students believed that they knew the topics and that the workshops did not have something new to offer them. The reality, however, was far different, as the workshops were very in-depth and offered students a wide variety of skills and competencies, which might not have been evident simply from the workshop title. In order to overcome this difficulty, and to engage students with the learning process, the Graduate School created a standard template for the workshop specification in which the research students could be informed in more detail of the learning outcomes, the activities, and the aim

Figure 7. A blended learning example of research students community in Moodle™



and the objectives of the workshops. By creating such a template, the student could make a more informed decision as to whether or not to attend the workshop and if (s)he would gain new knowledge and experience from it.

Solutions and Recommendations

It is likely that many research students have had user experiences in other Virtual Learning Environments (VLEs), such as BlackBoard®, BlackBoard Vista® and WebCT®, gained during their undergraduate studies or while earning their master's degree. The interface and the way that students participate in a discussion on the aforementioned VLE are slightly different from that of Moodle™. For example, in BlackBoard®, the users need to check the posts without receiving e-mails, but they should enter the online module and search under the module's discussion forums. In the case of Moodle™, the default option is for users to receive e-mail alerts for each post. Therefore, research students, who are unfamiliar with the Moodle™ environment, might complain about the vast number of e-mails that they receive and are, overall, reluctant to use it. In order to tackle this issue, the course leader needs to provide students with a step-by-step instruction booklet where some useful tips on how to configure Moodle™ will be illustrated.

Another issue that needed careful consideration was the university staff's familiarity with the Virtual Learning Environment. In our case, the Graduate School informed the university staff that their role in the Virtual Community would be that of a non-editing teacher. However, later throughout the academic year, many University staff started to complain that they received e-mails from the discussion posts even if they were not in the discussion group. That meant that they did not have a clear idea as to what the role of non-editing teacher entailed in Moodle™. Thus, although the role of the course leaders was not to support the university staff with tutorials and advice as to the role of non-editing teacher, they had to organize dedicated training courses and create supporting documentation to bring the university staff up to speed with the functionalities in Moodle™ that staff should have already been aware of. Another issue related to teachers was that some of them had the misunderstanding that their role in regards to the online course finished upon uploading the learning material. However, the role of teachers in facilitating discussion forums should be more than that of a mere provider of materials. The problem with this simplistic approach was that the teacher lost the continuous communication with students who eventually felt frustrated by the learning process. For that purpose, the course leaders checked regularly the discussion forums in Moodle™ and/or Facebook™ and if they could not respond directly to students' questions, they forwarded it to the appropriate person and/or encouraged other academics to provide an answer within the discussion forum. University staff are not always aware of technical and pedagogical issues related to virtual communities, the benefits of synchronous and asynchronous communication, and students' preferences for the new technological developments. Thus, apart from the existence of support via e-learning teams, universities are usually training new incoming academics on designing online courses and/or adopting blended learning. In our case, academics worked together in order to enhance teaching with the opportunities of blended learning, the new staff being more familiar with computer information technologies, whereas the senior staff had more experience on research related issues.

Another issue that the authors would like to mention is that some members of the community felt uncomfortable to post messages. There were a few examples where research students, despite the fact that they had access to Moodle™, were afraid to ask a question and they approached their Faculty administrator in order for them to post a question on their behalf. We assumed that the reason for this attitude was mainly that these students were afraid that their question would be deemed to be too simple and as such they would appear ignorant on the subject to their peers. As an example, this question was posted by a research administrator instead of the research student:

There is a question from a research student and we are wondering if you have similar issues or if you have any possible reply. The question: I'm planning a survey for part of my research and wondered if I could have access to a survey tool for collecting data online- does the university subscribe to Survey Monkey or anything similar and how would I get access to it?

In order to enhance the sense of community, and the relationships between university staff and research students, the Graduate School is organizing periodic face-to-face meetings and events in addition to workshops in order to keep the community focused and productive.

FUTURE RESEARCH DIRECTIONS

As the extensive use of ICT in Higher Education has changed the way that students, teachers, and other university staff communicate, one future step is for research students to create their own e-portfolio through their studies. By following this approach, supervision teams, along with research administrators, will have a complete view of the student's progress; individual feedback could be provided on students' projects and their personal development. E-portfolios could initially be restricted to private view and only university staff or other students would have access; but, after finishing their studies; the research students may make them available for public view. Overall, the e-portfolios could enhance the digital demands of research and they could be created by using platforms such as WordPress™ and/or Blogger™.

CONCLUSION

Over the last decades, the rapid growth of Internet access and Computer-Mediated Communication has created new possibilities for researchers to engage in supportive communication with a network of individuals coping with similar issues and challenges. The ability of Computer-Mediated Communication to transcend geographical and temporal constraints, the access to diverse sources, and the facilitation of more heterogeneous supportive relationships are possible through a virtual Research Students Community. University staff can collaborate with students in a flexible digital environment and consciously empower them. Research students could also exchange views and resources with their peers obtaining skills and knowledge and developing attitudes through collaboration. Research students will have a stronger sense of community compared with a traditional research environment, as they:

- Know who is the most appropriate person to assist them;
- Share their experience with other members of the community and are informed about other's views; and
- Are better supported in order to overcome their research project difficulties.

The Internet, as a medium for social activities, opens up entirely new features in academic society. However, academics should understand how people learn and how people can be facilitated to learn through ICT in order to create a pedagogically worthwhile virtual course/community. Socio-emotional and informational motivations mainly lead research students to be involved in a virtual community in order to discuss with others and/or collect information about common interests. The research students can discuss with the University staff and their peers, theory related to their research project through online discussion forums; or they can collect information independently by reading the uploaded material and others' messages to discussion forums or by searching on the uploaded web links available to them. Thus, research students do not have their supervisory teams as the only resource for collecting information. One issue for course leaders, however, is to keep students engaged in the process and to continue to pose questions, exchange views and ideas with the members of the community. The university staff have a significant role for students' involvement in a virtual community. They trigger a discussion, adopting an active and stimulating role by posing questions without being the direct provider for the research students' learning, or by posting external web links and/or documents. In a collaborative learning environment, the teaching style is changing from a directive and task-oriented (power-centered) supervision to a more non-directive and process-oriented (facilitation-centered) supervision. However, staff's beliefs, attitudes, and skills are potential points for a successful integration of virtual communities into research degree programs. University members have their own personal style regarding the way that they handle problem identification and solving, feedback, and support given to students, the way that they act as subject experts, and the way that they evaluate and respond to the students' work. The transition from traditional teaching to ICT-enhanced environments is not obvious and many staff are still hesitant or reluctant to adopt technology as part of their teaching. Thus, the participation of new staff along with senior lecturers would be beneficial for their active contribution to discussion forums, the enhancement of teaching with blended learning principles and their experience to overcome course difficulties.

KEY TERMS AND DEFINITIONS

Blended Learning: A combination of different pedagogical theories in a face-to-face learning environment with or without technologically mediated interactions between students, teachers and learning resources.

Computer-Mediated Communication: Two or more individuals communicate via separate computers through the Internet or an intranet.

Research: The process of carrying out a systematic and scientific investigation and publishing accurate results.

Social Learning: Occurs when the learners' behavior is changing from the environment through the process of observational learning, i.e. by observing how other learners behave around them.

Social Media: Platforms based on the Web 2.0 technology that allows the sharing of ideas, information and documents among users.

Virtual Community: A group of individuals who share the same interests and interact without geographical limitations through a social network system.

Virtual Learning Environments: E-learning platforms where teachers and learners have access to learning material, assessments, discussions, chat, etc.

Chapter 25
Internet-Based Technology Use in Second Language Learning: A Systematic Review

Shuyi Guan
University at Albany, State University of New York, USA

ABSTRACT

Ever since computer technologies were accessible to second language learners and teachers, various types of computer-assisted language learning (CALL) have been harnessed in the service of teaching languages. Most recently, the advent of online technologies has sparked CALL practitioners to integrate this powerful form of teaching and learning into language education. This paper synthesizes the extant research on these online language education activities and the state of current understanding regarding the potential of Internet-based teaching and learning second languages. The results of analyzing extensive studies of Internet-based second language learning reveals that Internet-based technology has been widely used in second language learning. In addition, Internet-based technologies are effective instructional tools for second language learning and teaching.

1. INTRODUCTION

Since computer technologies have been accessible to language learners and teachers, various types of computer-assisted language learning (CALL) programs have been harnessed in the service of teaching languages over the past 30 years. In the last decade, the advent of Internet technologies has sparked CALL developers and practitioners to integrate this powerful tool of teaching and learning second languages into language education. With the tools available today, online learning can be active, collaborative, and meaningful (Murugaiah & Thang, 2010).The present review examines extensively the existing research on online language education activities and the state of our current understanding regarding the potential of Internet-based teaching and learning second languages. This review focuses on three research questions: (1) how have Internet-based technologies been used in second language learning; (2) how have Internet-based technologies enhanced second language skills; and (3) how have Internet-based technologies changed students' and teachers' perspectives of second language learning and teaching?

DOI: 10.4018/978-1-4666-8246-7.ch025

2. METHOD

The technologies examined in this review refer to Internet-based technologies used in second language learning. This includes language course work like voice boards, wikis, blogs, course management tools (e.g. Blackboard System), and online language learning games. Any studies that were not using Internet technology as a central tool weren't included. To locate the research literature on Internet-based technology used in second language learning, I used the databases PsycINFO, ERIC, EEBSCO, and Education Full Text. The initial database search was based on a combination of the two groups of key words: (1) second language learning, foreign language learning, and (2) online learning, online teaching, and Internet-based learning. Manual search of references, such as the Annual Review of Psychology and the Handbook of Educational Psychology were also used to identify the exiting literature.

As a result, a total of 117 articles from 28 journals were selected for the review. Based on the number of articles cited in this review paper, the top six journals are Computer Assisted Language Leaning, ReCALL, Modern Language Journal, CALICO Journal, Computers in Human Behavior, and Computers & Education.

This article is organized as follows: First, the Internet-based technologies that are used in second language teaching and learning is described. Afterwards, the effect of Internet-based technologies in second language acquisition and students' and teachers' perspectives of online learning are discussed. Finally, the potential problems of online second language learning and implications for future work are provided.

3. INTERNET-BASED TECHNOLOGIES USE IN SECOND LANGUAGE LEARNING

The extensive Internet-based technologies have been used in the following four areas: (1) telecollaboration, (2) 3D virtual worlds, (3) mobile-assisted language learning, and (4) authentic online videos. Telecollaboration, such as Facebook, wikis, blogs, and podcasts have been widely used in second language learning, and there is extensive research on several kinds of online collaborative learning (e.g. Guth & Helm, 2012; Lee, 2009; Ware & O'Dowd, 2008). On the other hand, authentic online videos are a more traditional teaching and learning method that has been used even before the Internet technology emerged. Authentic online videos are usually used as a part of other online learning tools (e.g. Second Life and podcasts) but there is limited research on it. Existing research on each of these four areas are discussed in more details below, with starting with telecollaboration, the most widely researched type of technology used by second language learners and educators; and ending with authentic online videos, the least researched area of technology with this population.

3.1. Telecollaboration

Research has revealed that students reported positively about their language learning experience in online collaborative learning (see Lehtonen & Tuomainen, 2003; Guth & Helm, 2012; Lee, 2009; Ware & O'Dowd, 2008).Currently, Facebook is considered the most popular platform for online social networking among young generations, especially university students. It was found that students believed Facebook could be used as an online environment to facilitate English as Second language (ESL) (Kabilan, Ahmad, & Abidin, 2010). In addition, Facebook-integrated instruction can significantly enhance students' interest and motivation as it is already something they are familiar(Shih, 2011).

Wikis represent a unique type of collaborative learning where collaboration amongst peers can result in a project where multiple users are able to add their thoughts and ideas in order to create a comprehensive and combined final product(Bradley, Lindstrom, & Rystedt, 2010; Chao & Lo, 2011; Kessler, 2009; Lund, 2008). Wikis also hold the potential for collective knowledge advancement and language development (Lund, 2008). For example, Kessler and Bikowski (2010) reported a study on collaborative learning on a wiki in English as a Foreign Language (EFL) online course. Students performed five main language acts in the wiki: adding new information, deleting information, clarifying or elaborating on information, synthesizing information and adding web links. In performing these language acts, the students were able to contribute their own information to the group product, thus acting as a collaborative team member. The results showed that student interaction and language use benefited from the flexible learning environment.

The development of Web 2.0 technology brings blogs and podcasts into second language education. Blogs can be easily created and published instantly to the Internet, and then readers of the blog can leave comments in an interactive way by responding to the blog posts. A podcast is an online audio file that allows users to automatically receive available web-based audio files. Podcasting is appealing and supports language acquisition because it allows learners to listen to authentic recordings on a personal computer, as well as to record and publish their own talks (Lee, 2009).

Both reading and writing blogs, or listening to and creating podcasts are beneficial to second language learners. Lee (2009) conducted a study of a Spanish-American telecollaborative project through which students created blogs and podcasts. This study showed that effective use of online task-based instruction created a dynamic climate for interactive collaboration and afforded unique opportunities for both American and Spanish students to explore the target languages and cultures. The study also suggested that building interpersonal relationships and making personal commitments to online contributions are vital to successful intercultural exchanges (Lee, 2009).

Another study by Lee (2010) on blog technology used in second language learning revealed that by regularly creating blog entries there was a positive impact on learners' writing fluency and increased their incentive to write for a large audience. Students enjoyed the flexibility to personalize their blogs by choosing from a variety of free templates to make the design and layout attractive. This study also stressed that learners' critical thinking is essential for the implementation of blog and podcasting projects in second language instruction (Lee, 2010). When students published their work on a blog or podcast, they have to be active knowledge creators. They also had to write comments on other students' work which foster students' critical thinking and gave them a deeper understanding of the topic.

3.2. 3D Virtual Worlds

Online virtual worlds afford a number of interactional opportunities and resources for formal language instruction (Sykes, Oskoz & Thorne, 2008). For instance, Zheng and her collaborators (Zheng, Young, Wagner & Brewer, 2009) tracked Chinese learners of English as they interacted in a virtual world as a component of the English language class, and found that the amount and quality of learner participation far surpassed that of the face to face classroom. Another research (Jones, Squires, & Hicks, 2008) on an Internet-based spoken language learning system within a 3D online learning environment revealed that participants did improve their spoken language skills within the authentic and situated environment.

Second Life is a 3D virtual world where language students can communicate in real time with native speakers of the language they are studying (Jauregi, Canto, de Graaff, Koenraad, & Moonen, 2011). The effects of Second Life on students learning a second language include (1) reducing student anxiety and increasing motivation (Wehner, Gump, & Downey, 2011), (2) improving students engagement in language learning activities (Deutschmann & Panichi, 2009; Deutschmann, Panichi, & Molka-Danielsen, 2009), and (3) providing sufficient scaffolding, support, and feedback to students in order to promote further reflection (Grant & Clerehan, 2011). Learners of Spanish participating in language learning tasks in

Second Life reported positive outcomes in terms of rapport and productive language use (Jauregi, Canto, de Graaff, Koenraad & Moonen, 2011). Consistent findings were found in similar studies conducted by Peterson (2010) and Deutschmann & Panichi (2009) in similar studies with learners of English as a foreign language.

3.3. Mobile-Assisted Language Learning

With the development of mobile technologies and wide use of smart phones, *mobile-assisted language learning* (MALL) can be seen as a viable solution to blend a learners' learning environment into their everyday life. Mobile phones with Internet provide a unique opportunity to learn outside of the classroom, making learning available anytime and anywhere. In a study using MALL to learn English prepositions and Chinese idioms, mobile technology was a key element in supporting a creative output such as taking suitable pictures in an appropriate context to illustrate the prepositions or idioms under study (Wong & Looi, 2010). For example, during the lesson of learning English prepositions, such as "above, over, under, below", the students were assigned smartphones. The students were asked to venture out of the classroom to take photos that best demonstrated the usage of the individual preposition (Wong & Looi, 2010). They then posted these entries to a wiki space for peer sharing and review. A similar study was conducted in a Chinese language class where students were asked to become photo-bloggers by using their smartphones to take photos in their daily lives and make sentences that went along with the picture (Wong, Chin, Tan, & Liu, 2010). In these two studies, MALL is not only a content-based (delivery of learning content), but also a design-oriented (authentic or social mobile learning activities) method (Wong & Looi, 2010). MALL can be used as a tool to nurture students' self-directed seamless learning practices.

MALL is also reported to be an effective way for specific second language acquisition (Che, Lin, Jang, Lien, & Tsai, 2009; de Jong, Specht, & Koper, 2010; Demouy & Kukulska-Hulme, 2010; Kiernan & Aizawa, 2004; Kukulska-Hulme, 2009; Li et al., 2010). For instance, the effects of using vocabulary learning programs on mobile phones in relation to students' English vocabulary learning are investigated with Turkish college students (Basoglu & Akdemir, 2010). The results indicated that using mobile phones as a vocabulary learning tool is more effective than traditional vocabulary learning methods. Students spent more time studying with the mobile vocabulary learning tool than studying vocabulary on paper because it is entertaining and they can use it in their leisurely time (Basoglu & Akdemir, 2010). Nah (2011) showed that by using the Internet through a mobile phone to learn English as a foreign language (EFL), listening skills have significant potential, and language learners in South Korea hold positive attitudes towards using mobile phones as a tool for learning. According to this study, there are three factors that influence the learners' attitude towards the use of the listening website on a mobile phone. The first factor is the novelty of the new technology, and how students like the experience of talking in English through the mobile discussion board, completing the online tasks in their spare time and submitting the tasks online directly from their mobile phones. In addition, it is very convenient for language learners to participate in learning activities with less time or space constraints when they use their own mobile device. The third factor with the positive influence on attitude is the interactivity of the online learning tools because language learners are able to work hand in hand with their peers and teachers by interacting synchronously or asynchronously through short message services, mobile email, and mobile discussion boards (Nah, 2011).

Mobile phones can also be used in cross-platform language learning support systems, such as language learning service via interactive television (iTV). The mobile phone can support learners' understanding of TV programs by enabling them access to the summary of the program as well as access to difficult linguistic and cultural items, such as a sombrero if they are studying Spanish that may appear in the program (Fallahkhair, Pemberton, & Griffiths, 2007; Pemberton, Fallahkhair, & Masthoff, 2005).

3.4. Authentic Online Videos

According to the findings of existing empirical studies (e.g. Chen, 2011; Hada, Ogata, & Yano, 2002), subtitled second language videos are particularly useful for foreign language learning. For example, research has shown that the SynctoLearn tool, which provides synchronized subtitles, can be used as a supporting tool to help English as a Foreign Language (EFL). Students reduce their cognitive load and anxiety levels when tackling authentic videos (Chen, 2011). In addition, observing authentic subtitled videos "allow students to see a model of successful interaction, to be exposed to useful vocabulary and sentence structures within the context of an authentic situation while maintaining the need for them to generate their own original dialog" (Arslanyilmaz & Pedersen, 2010, p. 65). Other studies (e.g., Jauregi & Banados, 2008) reported that video-web communication tools can enhance the quality of the foreign language curriculum by facilitating an encouraging, virtual environment for meaningful interaction between nonnative and native speakers of Spanish.

Podcasting, another new technology of delivering audio and video files via the Web, is becoming increasingly popular among college students and has been used in educational contexts. The current use of podcasting in second language education is limited primarily to the delivery of recorded lectures in a portable, online format (O'Brien, & Hegelheimer, 2007). Researchers (e. g. O'Bryan & Hegelheimer, 2007) believe podcasting has the potential to not only act as a rich source of input and instruction for students in the language classroom, but also to eventually transform teaching all together.

4. THE EFFECT OF INTERNET-BASED TECHNOLOGIES ON SECOND LANGUAGE ACQUISITION

Extensive empirical research exists in comparing the linguistic outcomes of Internet-based second language courses to those of traditional face-to-face courses (e.g. Shih, 2011; Sagarra & Zapata, 2008). Internet-based second language instruction has been found to have positive outcomes in terms of students' language acquisition. For instance, a study of investigating student's oral communication skills of English in a blended Turkish college class showed that students had obvious development in their oral communication skills and felt positive about their perceptions of integrating technology in the lesson (Kırkgöz, 2011).

On the other hand, some research found that face-to-face instruction is more favorable in terms of linguistic development than online instruction. For example, Wang (2010) did a study that analyzed students' online utterances and offline interactions, and the results showed that online language learning promoted social interaction among students and their engagement; however, it did not automatically facilitate students in their adoption of active learning strategies. Therefore, this study did not find positive outcomes in terms of linguistic development.

More specifically, there are four basic language skills for second language learning: reading, listening, writing, and speaking. Reading and listening are the input in the process of second language acquisition, while writing and speaking are the output. In the next session, I will discuss how Internet-based technologies enhance these four second language acquisition skills respectively.

4.1. Reading

A study (de Milliano, Vermeer, Hootsen, & van der Werf, 2008) about the use of a dictionary with affix information of Dutch in an adaptive e-learning environment showed that learners made significant progress in vocabulary and reading, as a result of the use of an e-learning environment in which the difficulty of the texts was adapted to the level of the learners' vocabulary. Research (e.g. Al-Shehri & Gitsaki, 2010) also showed that ESL students who had access to the online dictionary during reading comprehension tasks performed better on vocabulary tests but spent more time on the reading task than the students who did not have access to an online dictionary. In addition, some of the studies (e.g. Arnold, 2009) showed that when students read online instead of printed materials, some of them purposely seek out more difficult texts to challenge themselves. That is also indicative of learners' growing motivation and self-confidence of online reading.

4.2. Listening

Developing listening comprehension skills is considered crucial for second language acquisition. Many studies about listening abilities are based on what learners report while listening to an oral message in a second language (e.g.Vandergrift, 2003). Roussel (2011) used a video recorded on the computer screen while L2 learners were listening to an MP3-track in German to objectively examine what learners do while listening. The video of the participants screen showed the movement of the mouse and its time-course, including the pauses and the backward or forward movements learners do in order to master their listening task. The study revealed that the opportunity to have personal control over information input given by the use of technology does improve learners' information processing (Roussel, 2011). In addition, McBride (2008) did a study on an online mini course designed to improve college EFL students' listening comprehension. The pretest and posttest results showed that students' listening comprehension improved with slow online dialogues.

Research also showed that there appeared to be higher vocabulary acquisition and knowledge retention with online listening tasks (Absalom & Rizzi, 2008). A study (Smidt & Hegelheimer, 2004) on authentic web-delivered video suggested that online academic lectures on ESL listening comprehension can improve the supplementary gain of vocabulary and listening comprehension.

4.3. Writing

In online writing situations, students are in great need of writing aids. Online writing technologies can provide not only writing guidelines to raise students' consciousness, but also learning resources and tools which include online translators, online dictionaries, phraseology, and wordlists (Kuo, 2008).

Writing skills and fluency have also been reported to improve as the result of online language learning activities (Ishihara, 2007; Lee, 2010) with learners effectively using the target language to manage the online conversations (Chun, 2008), and negotiate their instructional processes (Blake, 2000). The three most popular online writing activities in college language education--forums, blogs, and wikis—are favorable by college students, and help students improve their ability to differentiate English writing styles (Miyazoe & Anderson, 2010).

Synchronous online peer response groups have been increasingly used in EFL writing. A study (Liang, 2010) of synchronous online interaction among Taiwanese undergraduate EFL peer groups indicated that relationships among different types of online interaction depend on group makeup and dynamics.

4.4. Speaking

It has been frequently suggested that computer-mediated-communication (CMC) can help learners improve their oral proficiency (Abrams, 2003). Deutschmann and Panichi (2009)'s study revealed that students became more actively involved in online oral proficiency in the virtual world Second Life. In addition, spoken oral interactions between second language learners and tutors were found in online language learning environments (Heins, Duensing, Stickler, & Batstone, 2007). Synchronous learning management systems (SLMS), which include online chat, whiteboard, videoconferencing feature, addressed the vital need for real-time communication to support the students' gain of language skills (Wang & Chen, 2007).

5. STUDENTS' AND TEACHERS' PERSPECTIVES OF INTERNET-BASED SECOND LANGUAGE LEARNING

5.1. Students' Perspectives

Online language learners report favorably on the rapport-building that occurs in online language courses (Jiang & Ramsay, 2009) and increases in motivation (Thang & Bidmeshki, 2010), accuracy (Kelm, 1992) and overall learner satisfaction (Strambi & Bouvet, 2003). In addition, Alameen (2011) reported that Web 2.0 digital stories used by English language learners provided an interactive venue for building learner communities, fostering collaboration, engaging learners in multi-literacies, and creating opportunities for global audience interaction and feedback.

The quality and amount of interaction among students is widely acknowledged to be an important indicator of successful online language learning experiences. There are studies which show that the experience of increased asynchronous online interaction with peers and teachers in the Internet-based second language course design produced a change in the students' perceptions towards the necessary interactive elements. For example, the usage of forums, blogs, and wikis in EFL-blended learning courses have been explored in research and the results revealed students' positive perceptions of the blended course design with online writings (Miyazoe & Anderson, 2010). In this study, the blended learning course design includes weekly face-to-face instruction and out-of-class online writing activities. Forums were used for topical discussions; blogs were used for an optional free writing activity; and wikis were set up in order to conduct a collaborative translation from English to Japanese. Throughout the course, the instructor did not participate in the online activities, but carefully observed what was happening in the system. The questionnaires and observations showed that the different activities provided by the blended course design were not only challenging, but were fun for the students to complete.

Another study on the use of the WIKI in a large blended learning class showed that the online learning experience extended the classroom beyond the physical space and engaged students in interactional communication in the second language, encouraged them to find the meaning of the words, and challenged learners to find solutions to real life problems around them (Aborisade, 2009). A study (Huang, Lin, & Chiang, 2010) of web 2.0 used in a Chinese foreign language classroom also indicated that the instructor and students alike responded positively to online learning, which suggests that web 2.0 is a good tool in promoting effective learning of Chinese.

In addition, there are many studies about students' satisfaction or perceived effectiveness of a blended second language class. For example, Jochum's (2010) study of online Spanish instruction revealed that students' comfort levels significantly increased in writing in Spanish and taking online Spanish courses. Also, the students appreciated the online format in comparison to a "normal" second language learning class structure and felt that they benefited from it.

As part of a larger study examining the influence of popular culture and the internet on heritage language development, Lee (2006) explored the social networking practices of two Korean-American heritage language learners. Employing case studies of her two siblings, the author investigated their linguistic and pragmatic practices. Data suggests that online social venues provided them with authentic opportunities to use the language and to support the development of their online social networks. Online practices enabled them to participate in social interactions without the pressure of spelling words correctly. But they were also frustrated because they could not distinguish between correct and incorrect forms of the language.

5.2. Teachers' Perspectives

With the increase in Internet technologies in asynchronous instruction, questions concerning the role of the instructor as it determines the quality and impact of learning (Meskill & Anthony, 2007). Comas-Quinn (2011) argued that while technological challenges and the sheer amount of change that teachers were faced with were largely responsible for some of the negative attitudes reflected in teachers' opinions about the course. A less obvious explanation for their unenthused attitudes might be found in the way that learning, teaching and training are conceptualized by both teachers and the institution. Belz and Muller-Hartmann (2003) examined how social, cultural, and institutional affordances and restrictions in a telecollaborative foreign language learning partnership shaped the group of online teachers.

Some critics have commented that online courses may discourage teacher-student interaction, which is considered by teachers and researchers as an important element in language learning. For example, Ng, Yeung, & Hon (2006) found that the amount of interaction between the student and teacher may depend solely on the students understanding of the targeted language.

6. CONCLUSION AND IMPLICATIONS

How have Internet-based technologies been used in second language learning? It is clear that Internet-based technologies have been widely used in second language learning. The Internet-based technologies that are reviewed in this paper include at least four types, telecollaboration, 3D virtual worlds, mobile learning, and authentic online videos. There are some other technologies that have not been discussed in this paper because they have not been extensively used in language education, and also there aren't enough empirical studies on those technologies. For example, the MOO is a text-based online virtual reality system in which multiple users are connected at the same time. Although there is limited research on it, it has shown that MOOs are very suitable as a venue for culturally and linguistically challenging language learning students through online tandem partnerships (Kotter, 2001). In Kotter (2001)'s study, a MOO-based language learning project was used in a tandem English-German learning class. The result showed that partners improved their own communicative competence by conversing with native speakers in a non-threatening environment, and by receiving instant and extensive feedback.

What is research evidence on Internet-based technologies enhancing second language acquisition from both students' and teachers' perspectives? It is widely accepted by researchers that Internet-based technologies are effective instructional tools for second language learning and teaching. Most of researchers agree that second language learners benefit from Internet-based technologies. However, few studies did question the value of implementing Internet-based technologies into second language learning.

6.1. Potential Problems of Internet-Based Second Language Learning

Murphy (2009) reported the benefits, challenges and solutions of using synchronous online communication for learning French as a second language.

Benefits ranged from students' sense of freedom in the class, feelings of confidence to enhanced self-esteem along with motivation to complete the work because of the factor of peer learning. Challenges included teachers' inability to keep up with the work, audio and technical problems and scheduling. Solutions included technical support and using students as moderators to relay incomprehensible messages from the teacher to other students.

Dalarna University in Sweden, offered a web-based English learning platform including asynchronous document exchange and collaborative writing tools, e-mail, recorded lectures in various formats, text chat, and audiovisual seminars. The study (Cunningham, Fagersten, & Holmsten, 2010) of this learning program revealed four communication problems experienced in this kind of education: (a) technical problems; (b) students not understanding the teacher because of poor sound conditions or poor perception skills in English; (c) students not understanding fellow students because of limited proficiency on one or both parts; (d) the teacher not understanding the student because of the student's unintelligible pronunciation, in combination with less than optimal sound conditions.

6.2. Implications for Future Research

Based on the journal articles that have been reviewed in this paper, most of the studies focused on college students' second language learning. There are quite a few studies about online language learning for K-12 students. Future research should go beyond college students, and pay more attention to K-12 students' second language acquisition and learning outcomes in Internet-based language learning.

Research should also go beyond ESL and Spanish and focus on other second languages. For instance, there are few studies on Chinese, which is one of the most popular languages in the world. Although "learning second language online" can be a general research topic, different languages have very distinct features that may bring diverse outcomes when learning the language online.

In addition, more research needs to be conducted in specific language skills, such as listening and speaking. We have reviewed reading, listening, writing, and speaking abilities as the outcomes of online learning. There are plenty of studies on second language reading and writing skills (e.g. Bloch, 2009; Kilickaya & Krajka, 2010; Liu, Chen, & Chang, 2010; Ma & Kelly, 2006), but there are not sufficient studies about online listening and speaking. The instruments and measures for analyzing online listening and speaking is limited, and it is not easy to evaluate students' listening and speaking ability compared to reading and writing. Future research should examine not only reading, vocabulary, grammar, writing, and spelling, but also oral speaking and listening comprehension.

Chapter 26
Assistive Technology and Distance Learning:
Making Content Accessible

Kathleen Bastedo
University of Central Florida, USA

Jessica Vargas
Rollins College, USA

ABSTRACT

For those with disabilities, distance-learning courses can provide access to a world that was once inaccessible. Online learning becomes a possibility and for many a gateway to contributing to the world around them. However, there are many points to consider when ensuring accessibility in distance-learning courses. By exploring the current research and trends, this chapter reviews learning management systems, learner interaction styles and tools, and methods to design accessible course materials. It provides the educator with not only a working vocabulary but also with strategies and implementation methods for ensuring accessible content in online learning.

INTRODUCTION

Distance learning has been in existence for almost 150 years (Phillips, 1998), but it has never changed as quickly as it has over the last 20 years. The advent of the Internet, the availability of learning management systems (LMS), the variety and ease in use of all types of media (e.g., audio, video, social media), and the changing face of today's learners are all reasons for these developments. This chapter explores these changes as well as the latest trends in distance learning, the differences between online learning modalities among the K-12 and the higher education environments, and how the needs of all students, including students with disabilities, can be met online today and in the future.

DOI: 10.4018/978-1-4666-8246-7.ch026

Objectives

The objectives of this chapter are:

- Investigate the types of interactions in distance learning
- Identify the distance learner and their technological needs
- Distinguish between two classifications of LMS (i.e., open vs. closed or proprietary)
- Recognize features of learning management systems that incorporate accessible design
- Identify the laws related to accessibility of distance learning materials in K-12 and higher education
- Apply accessibility best practices to the creation of distance learning course materials

DISTANCE LEARNING

Historical Overview

As mentioned, distance learning has changed. Correspondence courses, which have been around since the late 1800s (Phillips, 1998), were perhaps the first noted distance learning courses available. Communication between instructors and students was slow and materials were transmitted using the United States Postal Service. With the advent of the Internet, communication between online learners and instructors occurs at lightning speed. Instructors are no longer restricted to the physical classroom; they can pursue academic ventures while delivering a class literally a world away. Likewise, students who lead busy lives can attend classes and advance their careers at times that are convenient for them. The very nature of this modality has transformed how instructors teach and how students learn.

In addition, educational institutions began to invest in distance learning in order to reach a larger demographic that could no longer be accommodated at a physical site (e.g., lack of physical classroom space). Other students soon found reasons to sign on as well. Non-traditional students who were unable to pursue a degree in the face-to-face setting (e.g., individuals working full-time, single-parents) were afforded the opportunity to do so online. Student choices towards instruction expanded because of the availability of these types of courses, and eventually non-traditional students began taking online education as a matter of convenience (Moskal, Dziuban, Upchurch, Hartman, & Truman, 2006). Due to student demand, many institutions began to offer more online courses. As new technologies became embedded into American culture, students began to expect instructors to incorporate technologies into the classroom and deliver more courses online. As the number of these courses increased, the number of students taking these courses also began to rise. According to the 2010 Sloan Survey of Online Learning conducted by the Sloan Consortium, "in fall 2009, colleges—including public, nonprofit private, and for-profit private institutions—reported that one million more students were enrolled in at least one Web-based course, bringing the total number of online students to 5.6 million" (as cited in Kaya, 2010, p. 1) from the previous year. Demographics have also changed to reflect that most traditional students now take some form of distance education study (Zatynski, 2013).

Distance Learning and Disabilities

This leads to a discussion about students with disabilities and education. Prior to 1970, it was difficult if not impossible for many students with disabilities to attend public school, never mind institutions of higher education. In response to this situation, Congress first passed the Education for All Handicapped Children Act (later known as the Individuals with Disabilities Education Act of 1990 or IDEA) in the mid-1970s to ensure that students with disabilities would have access to a free and appropriate public education or FAPE (National Dissemination Center for Children with Disabilities, 2012; Special Education News, 2013). With this law in effect, more students with disabilities began to attend K-12 schools. Provision of transitional services from K-12 to institutions of higher education in the 1997 amendments to IDEA, along with Section 504 of the Rehabilitation Act (U.S. Department of Labor, 2011), and the ADA, helped to increase the number of these students applying to institutions of higher education (U.S. Department of Justice, 2009; U. S. Government Accountability Office, 2009). Given the combination of these factors along with the proliferation of online course offerings, it is not surprising that institutions have reported an increase in the number of students with disabilities not only attending institutions of higher education, but taking online courses as well. In 1999, the U.S. Department of Education's National Center for Education Statistics (NCES) reported that "the numbers of students with disabilities transitioning from high school to higher education is expected to increase even more in the decades to come because of increased implementation of federal laws" (Justesen, Stage, & de la Teja, 2013). The strength of these laws together is intended to ensure that all students with disabilities have the right to the same educational opportunities as the rest of their peers.

The benefits to taking distance education courses for students with disabilities are similar to their peers without disabilities such as the increased flexibility and convenience online courses provide. Learning from home provides many of these students with the ability to work in familiar surroundings and function with the equipment and support systems they already have in place, especially if they are physically unable to attend school (Woods, Maiden, & Brandes, 2011). Due to these reasons, distance learning appeals to students with or without disabilities.

Distance Learning Defined

Distance learning is a method of instruction where the student does not always have to be present in the physical classroom in order to interact with the instructor. Some or all course content can be delivered over the Internet using an LMS. The LMS provides instructors an area to place their course materials online and for students to receive that instruction while interacting with other students and/or the instructor. Distance learning utilizes two modes of learning: synchronous and asynchronous. Synchronous course components require instructors and students to be at their computers at the same time (e.g., an online chat). Instructors can also provide learning activities, quizzes, discussions, etc. that students can access at various times independently or asynchronously (e.g., discussion board interactions).

In higher education there are generally two types of classes designed for distance learning: fully online courses and blended courses. For fully online courses, all course materials (e.g., assignments, interactions, assessments, grades) are provided and submitted via the online environment (e.g., LMS) without a face-to-face component. There is no specific face-to-face time as everyone meets virtually in the designated online environment, though some courses may require minimal face-to-face requirements (e.g., attendance at proctored examinations).

The second mode of distance learning courses common in higher education is called a blended course (also known as a hybrid or mixed-mode course), which consists of both face-to-face and online class components. At the University of Central Florida, where online classes have existed since 1996, students not only succeed better in a blended format, but also both faculty and students alike preferred the blended method over either fully-online or fully face-to-face classes (Moskal et al., 2006). It is up to the instructor's discretion which components are completed online and which components are completed in the face-to-face environment.

Distance Learning in the K-12 Setting

Although distance learning has existed in higher education longer than in the K-12 environment (U.S. Department of Education, 2010), online courses and programs have been increasing rapidly at the K-12 level (Barth, Hull, & St. Andre, 2012). Even though the idea of distance learning in the K-12 environment may seem unfamiliar or new to some, the following provides a list of reasons why online learning has been emerging in this environment:

- **Creation of a Virtual Learning Environment:** for students who may not have the opportunity to take a course due to the lack of the availability of a trained local instructor or the lack of class availability or for students who have a medical condition or a physical disability that prevents them from attending class.
- **Access to Higher-Level Credited Courses:** for those students who have the capability to advance further while still taking classes in the K-12 environment.
- **Increased Access to Education for Nontraditional Students:** for students who may have left schooling for a variety of reasons (e.g., dropouts, juvenile delinquency).

Currently, most K-12 environments offer face-to-face courses and online courses. Blended learning in K-12 is when a student takes a combination of both face-to-face classes and fully online courses during the school year. Reduced seat time, while common in the higher education setting, is not typically a component of blended learning in the K-12 setting.

In higher education, the same instructor teaches both components in the face-to-face and in the online environment for both blended and fully online courses. In most cases the onus of designing these courses falls largely to the instructor teaching these courses. In order to meet the educational needs of faculty members slated to teach online, many institutions offer professional development programs while other institutions expect faculty to learn on their own. Course content usually remains the intellectual property of the instructor who created the course, though there are exceptions to this practice.

In the K-12 environment, however, online courses are often created and delivered by for-profit, third-party vendors. These instructors are generally not affiliated with the school system that the student attends. Also, vendors have the ability to purchase courses from other vendors (Staker & Horn, 2012). In fact, there is a movement by some K-12 institutions that include a clause for students to take an online course as a graduation requirement. For example, beginning with the 2011-2012 school year, high school students in the Florida Public School system are required to successfully complete one online course during high school before they graduate (Online Sunshine, 2012).

Despite all the complexities facing the institutional implementation of these courses, today's instructor must also consider how to accommodate the various learners in his/her classroom. In a traditional face-to-face classroom environment, instructors have multiple avenues in place, such as the Individualized Education Plan (IEP) at the K-12 level and the institution's disability services office in higher education, to assist students with disabilities. However, as more and more digital materials are added to courses, instructors are less equipped to ensure that students with disabilities are able to access this type of content. Fortunately, growing trends in distance learning and accessibility can be applied to meet the needs of students with disabilities and professionals online.

Quality Control of Online Courses

This discussion also raises the salient question: How does one control the quality of online courses? In the K-12 environment this has become a point of concern with more research necessary to fully answer the question (U.S. Department of Education, 2010). In higher education, one organization has been working towards that goal for well over 10 years. Although it's not the purpose of this chapter to instruct how to build and design distance learning courses from scratch, becoming familiar with the Quality Matters Program (2013; http://www.qualitymatters.org/) will assist instructors in doing so. The Quality Matters Rubric© contains several accessibility-related topics that are used to evaluate the design of a course in addition to covering many other content areas. There are also many other rubrics that are available for free online, but care should be taken to review these rubrics to make sure accessibility is addressed. With this push towards online instruction, it can be safely assumed that distance learning courses are here to stay. However, it is up to individuals on the forefront to make sure online content remains accessible to students with disabilities.

Differences Between Face-to-Face and Online Course Components

Learning management systems have become synonymous with distance learning courses because most courses today are embedded into one of these systems for several reasons. For example, they help keep the course organized, track student data, and provide the tools to help students interact with the instructor and each other. Prior to delving into the discussion about the accessibility of LMS, the primary differences between face-to-face and online course components are outlined.

Time: Within the face-to-face environment, class meetings and learning opportunities are constrained by the physical space and time designations placed on a course. It is difficult to replicate or provide the information for those students who miss instruction in the face-to-face setting. In the online environment, the information has been provided in a digital format so students can easily locate the information within the course when they need to and have the option of viewing the information at their own convenience within a given period of time.

Location: Face-to-face classes require a dedicated physical space, which may limit the growth of a university or college due to space constraints. Turning to online has meant that faculty and students do not require a physical learning space and thus classes are not limited to a set date, time, or place. Class meetings generally occur completely inside an LMS. Online classes also appeal to students with mobility concerns (e.g., lack of transportation or have a difficult time maneuvering across large campuses). Undergraduate data shows that "students with mobility disabilities enrolled in a distance education course more often than students with no disabilities (26 percent compared with 20 percent)…" (Radford & Weko, 2011, p. 3).

Discussion: Regardless of modality, meaningful class discussion that includes everyone's participation is difficult to engender. In-class discussions must occur within a designated class time so that students and instructors can interact and learn from each other but it's rare that all students are able to participate given classroom time constraints. It can be especially difficult for someone with learning disabilities or speech difficulties to formulate an answer in this setting. Discussion in the online environment generally takes place over a much longer period of time providing students with the time they need to better formulate an answer.

Assessments: It is generally easier to provide proctored exams in a face-to-face environment because instructors have the opportunity to monitor students in person, within a specific setting. When moving assessments into the online environment, there is a heightened concern for cheating. The following are a few strategies developed to help combat cheating in the online environment:

1. Not using the same exam over and over,
2. Shuffling the order of the questions (Harmon, Lambrinos, & Buffolino, 2010),
3. Include higher level types of questions, and
4. When feasible, assign an authentic assessment such as a project, an essay, or a research paper (Olt, 2002; Watson & Sottile, 2010).

Community: The opportunity to build a learning community is available in both mediums. So despite the concern that the online modality is considered to be less personal, instructors find that students who may not ordinarily speak up in class find the online modality space as an opportunity to contribute. In many cases, instructors report that they often feel they know their online students better than students they only see in the face-to-face environment.

LEARNING MANAGEMENT SYSTEMS CLASSIFICATION

Enterprise vs. Open-Source Systems

Over the years, distance learning systems have been created to house online course tools and materials. Generally termed a "learning management system," they are also called "course management systems" or "virtual learning environments." They are available from a variety of vendors and not surprisingly, supplying these systems has become a multi-billion dollar industry. These tools allow educators to:

1. Deliver content,
2. Manage assessments,
3. Provide materials for students to download,
4. Integrate other learning technologies,
5. Create opportunities for online learning activities,
6. Encourage communication exchanges between instructors and students, and
7. Disseminate grades to users.

These systems can be proprietary (closed source) or open source. Proprietary systems mean that the public does not have access to the source code that is used to run the program (e.g., Blackboard Learn®). Open source means the code is available to the public who has the ability to customize, change, or adjust the code as they need. The trend is toward LMS that are cloud-based, offer open-source code access, customer support, and a fee for use (e.g., Canvas®, D2L®). Even though a system may be open source, depending on the sophistication of the LMS, it is not always better to be responsible for updating the code. It may be better for the institution to pay for the product vendor to host the system and let the vendor update the code as well. The information in Table 1, though by far not an exhaustive list, includes the LMS (and related information) that are most often used in distance learning in both the higher education and the K-12 environments.

Many of these vendors are aware of the limitations of their systems and work continually with their user base to improve the system experience. Whichever system institutions choose, it's best to maintain a close working relationship with the respective product vendor. Most of the vendors will address accessibility issues as they arise and several have won awards related to accessibility. Desire-2-Learn®, for example, has been awarded the Gold Level NFB-NVA Certification by the National Federation of the Blind twice (Desire-2-Learn, 2013). However, some components of an LMS may not be accessible and seeking accessibility is always an ongoing process especially as new tools are added to the systems. In addition, most LMS also offer a free option to use their system to try it out to conduct a pilot study so testing can occur before purchasing or investing time, energy, or money in such a product.

Table 1. LMS comparison list

LMS	Description	Benefits	Challenges
Blackboard Learn® (http://www.blackboard.com/)	Blackboard™, founded in 1997, has the largest user base to date (usage has been adopted by over 60 countries), but has been seeing a steady decrease over the last few years with the availability of new systems (Chung, Pasquini, & Koh, 2013). It is a proprietary (closed source) system that can be self-hosted by the institution or hosted by the company. Institutions pay according to the number of licenses determined by user enrollments.	Can support institutions with a large amount of users	Currently the most expensive of LMS available to implement Features available according to pricing structure
Desire2Learn® (http://www.desire2learn.com/)	Desire2Learn®, founded in 1999, is an open source, cloud-based learning system. The institution pays for its use, but its open source ability allows end users to help customize its features as necessary.	Full customization options from system-wide to course level Can support institutions with a large amount of users	Customization options can be overwhelming for those with limited experience
Canvas® (http://www.instructure.com/)	A relative newcomer, Canvas®, founded in 2008 by Instructure, Inc.™, is an open source, cloud-based system. The LMS can be self-hosted for free and the institution using the system can update the code or the institution can pay the company to host it for them and to make updates. It also incorporates Web 2.0 functionality and tools.	Ease of use for faculty and students Works best for smaller institutions Content creation is simple based on Web 2.0 technologies Newest modifications go to cloud-based customers first	Customization occurs on a system level rather than course level Third-party tool integration can mean commonly used features go down with minimal available support to fix those items
Moodle® (https://moodle.org/)	Moodle®, founded in 2002 by Martin Dougiamas (Moodle, 2012), is a free, open source, self-hosted LMS. It has enjoyed widespread adoption of its tool mostly in the international markets.	Cost is minimal to implement Works best for smaller institutions (Smith, 2011) Maintains a large community base of programmers dedicated to its continual improvement	Lack of human resource capabilities
Sakai® (http://www.sakaiproject.org/)	Sakai®, developed by a group of colleges and universities in 2004 (Unicorn, n.d.), is a free, open source LMS used for teaching, research, and collaboration in what is called a Collaboration and Learning Environment. It can be self-hosted for free or an institution can pay a service for hosting purposes. Since one of its goals is for use in research, the system contains a system-wide wiki, mailing list distribution, archiving and a rich site summary or an RSS reader. Yet it contains many of the same features available in other LMS (Sakai Project, n. d.).	Cost is minimal to implement Maintains a large community base of programmers dedicated to its continual improvement	Complicated programming language makes it difficult to manage and implement Lack of human resource capabilities

INTERACTIONS IN DISTANCE LEARNING

As distance learning began to evolve and options of LMS became available, there were concerns related to the type of interaction available in the online classroom. Critics worried that with correspondence courses, students were only self-directed learners who missed the opportunity to reflect and to reconstruct their knowledge when confronted with multiple viewpoints. This lack of interaction was often cited as a barrier to distance learning (Parker, 1999). Improvements in technologies over the years have improved the quality of interactions in distance learning. There are five types of interactions that instructors can incorporate into the curriculum. The first three are the most common types of interactions, while the last two interactions listed have evolved along with distance learning and the Internet.

- **Learner to Instructor:** The most common interaction, this requires that interactions occur between the instructor and the learner and vice versa.
- **Learner to Learner:** Regardless of instructor intent, students will inevitably interact with each other. These interactions become more meaningful with guidance from the instructor.
- **Learner to Content:** Learners interact with the content either by reconstructing its meaning or working with problems that allow students to further engage with the content.
- **Learner to Tools:** Learners engage with the tools selected for the classroom curriculum and learning opportunities. There are a wide variety of tools available ranging from Web 2.0 technologies to hardware and software.
- **Learner to Environment:** The learner engages with the environment via different classroom modalities (e.g., face-to-face classroom, blended/hybrid, and fully online), which dictates how the students will engage in the classroom.

Distance Learning Tools for Interaction

There are a variety of tools that assist in facilitating interaction in distance learning. These tools have been classified into two categories: asynchronous and synchronous technologies and are defined as follows:

- **Asynchronous Technologies:** These technologies have an anytime, anywhere component that allows a variety of learners to engage in the online environment at various times. They have the greatest capabilities for breaking down learning barriers as they allow the user to access online course content at their own convenience. These tools include email, discussion boards, social networking sites, Google Drive™, wikis, and other online collaborative methods (e.g., e-portfolios, audio/videos).
- **Synchronous Technologies:** These technologies provide learners the opportunity to engage during a set date and time. The strength to these technologies is that interactions occur simultaneously and questions/answers can be delivered within the construct of the activity. Furthermore, these technologies solidify learning communities quickly by having students engage with each other and the instructor (e.g., chat, video or web conferencing, and live podcasts).

After all this discussion about interactions in distance learning and the tools that facilitate those interactions, it may be difficult to decide when and which tool to incorporate into an online course. Table 2 identifies the type of interaction, the available tools, and the benefits to teaching and learning. Because many of these tools overlap, choose the interactions and tools that best meet the need of the learning objective.

Table 2. Matching interactions with the tool

Type of Interaction	Asynchronous Tools	Synchronous Tools	Value of Teaching	Value of Learning
Learner to instructor	Discussion board Email Course Calendar Rubrics Announcements	Videoconferencing tools (e.g., Skype™, Adobe™, Connect®, Collaborate®, Google Hangouts™) Live Chat/Instant messaging	Provides "written" documentation of communications. Identifies potential need for intervention.	Enables students the opportunity to engage with the instructor.
Learner to learner	Discussion board Email Text Peer Review	In-class peer review Live Chat/Instant Messaging Videoconferencing tools Group projects	Provides opportunities for virtual coaching and peer mentoring. Creates a learning community.	Encourages peer sharing of information and experiences.
Learner to content	Rubrics Games HTML pages YouTube™ Weblinks Podcast PowerPoint®	Live-streaming lecture (e.g., lecture capture, webinars) Videoconferencing tools PowerPoint®	Solicits understanding from learners on a specific topic	Provides information that is integral in student learning of class material.
Learner to tools	Blogs Wikis ePortfolio	Paper-based assignments	Aggregates student learning in one centralized location.	Allows for student-generated content. Students are allowed an opportunity to demonstrate learning in a tangible format, which maximizes retention.
Learner to environment	LMS Social networking applications (e.g., Twitter™, LinkedIn™, Facebook™, etc.)	Videoconferencing tools Face-to-face classroom time	Allows learning to occur in a structured environment.	Creates opportunity for students to learn within a community.

ACCESSIBILITY AND ASSISTANCE TECHNOLOGY FOR STUDENT LEARNING

Access is providing the flexibility to accommodate the user's needs and preferences. The following is a list of users who need various types of access to the Internet and online course materials. Namely, students with:

1. Visual impairments,
2. Hearing impairments,
3. Learning disabilities,
4. Mental disabilities,
5. English as a second language,
6. Physical impairments and
7. Slow connection speeds.

At the K-12 level, an IEP must be completed on an annual basis for qualified students. It is the IEP team's responsibility to determine how the student will access the curriculum and if any assistive technology (AT) is needed based on the student's goals. In higher education, there is no IEP available to students; therefore, students must learn to become self-advocates and meet with the institution's student disability office as needed. There are typically a few accessible computers stations scattered across campuses and at the institution's student disabilities office, but these stations are generally designed and may not meet the specific needs of each individual student with disabilities.

Students with disabilities who complete high school and move onto higher education are often faced with an additional set of challenges. Some students will be reluctant to report their disability for fear of non-acceptance by other students. Some students may be unable to develop the necessary self-advocacy skills in order to become successful on their own. In other cases, some faculty perceive students as trying to abuse the system to obtain unnecessary accommodations related to homework and test taking. Students who are not officially diagnosed with a disability may not be eligible to receive services from the institution's disabilities office (Justesen et al., 2013). These are just some of the obstacles students with disabilities attending higher education will face on their own.

Four Components of Access

In addition to self-advocacy skills, students will also need access to the following four components of access in order to help them be successful when taking distance learning courses. They are computer access, browser access, access to the tools located within the LMS, and online course material accessibility. The following information provides a breakdown of these components.

Computer Access

Computer accessibility also varies depending on the student's type of disability. Students with visual impairments may require screen enlargement programs so they can read the print on a screen. For web pages, it is easy to enlarge the text on a browser page by pressing the control and the plus key on a PC running Windows® and the command and the plus key on an Apple Macintosh®. Further evaluation by trained professionals may be necessary to accommodate other visual impairments. For a student who is blind, screen reading software such as JAWS® for Windows® may be required.

Accommodating students with hearing impairments can be a daunting task due to the increase in the availability and ease of use of media tools. A transcript makes it easier for the instructor to film a video or record an audio clip; and it also provides the basis for captioning, which is required by law to assist students with hearing impairments. Captioning also helps students who are speakers of English as a second language and for students who work in noisy or quiet (e.g., library) environments.

Learning keyboarding skills at the K-12 level is critical for students to be successful at the college level. For some students with disabilities computer access may be the only way they can make significant contributions to classroom or homework activities. Proficiency using the computer and the Internet (e.g., e-mail, search tools, creating/viewing web pages, using social media, and media in general) are skills today's students need to succeed in a competitive work force. For students with physical disabilities, alternate access may be required. Assistive equipment can range from an adapted mouse, an alternate or an onscreen keyboard, special scanning software, or a specialized switch that can be activated using various body parts (e.g., hand, finger, head, or foot). The AT used on campus may be unfamiliar to a student who requires access so training may also be needed.

Web Browser Access

A web browser or browser is a software application that provides users with the ability to access, view, and retrieve materials on the Internet. Some of the common browsers include Mozilla Firefox®, Microsoft Internet Explorer®, Safari® by Apple™, and Google Chrome™. In order for individuals with disabilities to be able to use the same materials, browsers must be equipped with accessibility features. Most browsers have these features built-in, such as: the ability to adjust the size of the text (zoom in or out), the ability to change the color or improve color contrast, and access to keyboard shortcuts.

Learning Management Systems

The last component that needs to be evaluated for accessibility in the online learning environment is the LMS that is being used by the institution. In most cases users do not have a say as to which LMS will be supported by the institution. However, it is still the responsibility of the institution to ensure LMS accessibility to its students.

Unfortunately, when some LMS are being created, developers do not always consider accessibility during the design phase. For instance, the discussion tool can be difficult for a blind student to access or for those who have a learning disability to follow the flow of a particular discussion. Likewise, chat tools tend to be overall inherently inaccessible for students who are blind. In both cases, it may be necessary to change the assignment interaction strategy to one that is accessible (e.g., use the email tool instead), until the tool is retrofitted for accessibility by the LMS, or until another accessible tool is found and can be used in the meantime. Assessment tools are generally accessible and most LMS provide a way to extend time to one or more students as needed. There continues to be improvements in these areas, but institutions need to be diligent and maintain an open line of communication with the LMS, in order to address issues as they arise.

Course Page Accessibility

When it comes to the creation of accessible online course materials, it is the responsibility of the institution (both the K-12 and higher education levels) and the instructor to provide these materials in accessible formats. In many cases instructors are not aware of the strategies or techniques that should be used to assist students to easily read or access online materials. Some things to consider before creating content are: style elements such as color and background as well as date format, layout, and organization of course pages, which all play an important part in making digital content accessible. If course materials are located outside of an LMS, for example on a college or department website, then these pages must be accessible as well. There are a variety of tools (some of the most common tools are listed in Table 3) to ascertain whether or not the content created is accessible. One great tool for reviewing web accessibility of content is WAVE (see http://wave.webaim.org/ for details), a free evaluation tool for checking HTML files. Use this tool and others similar to it to check the accessibility of all web pages.

It is becoming not only easier to add multimedia components to course materials, but it is also easier to add multimedia components to assessments. Therefore, keep in mind that the instructor is responsible for making these components accessible as well. For example, any images that are added to assessments must have alt text, audio portions must include text transcripts, and videos must have captions. There is a multitude of resources available on the Internet designed for this purpose; however, if the instructor is not sure where to begin, Table 3 contains a list of concepts and best practices in order to get started.

RESOURCES FOR ACCESSIBILITY IN DISTANCE LEARNING

Gaining access to professional organizations can also help the instructor keep current with how AT is evolving in the distance-learning medium. Table 4 contains many online resources and several helpful organizations. There are also more resources located in the *Additional Readings* section of this chapter.

Table 3. Best practices for accessibility

Concept	What to Do
Formatting Text	Avoid using small font sizes. Use fonts that are basic, simple, and easily read on a computer screen (e.g., sans-serif fonts). Use a limited number of font styles. Most web developers will only recommend 2-3 fonts per page of onscreen content. Only underline text when it is a link. Use bold for emphasis instead. Use headings to show topics and subtopics within the content. Use WebAim Color Contrast Checker (http://webaim.org/resources/contrastchecker/) to ensure high contrast between the text and the background (e.g., avoid using dark blue text on a black background). Avoid using only color to denote importance (e.g., using red text, color blind students will see grey instead, which depending on contrast may or may not be helpful.)
File Formatting	Use standard file extensions that work for all Windows®, Macintosh®, and Linux® users, including mobile technologies. PDFs should be scanned in as Optical Character Recognition (OCR) so it is read as text and not an image. Use the built-in Microsoft PowerPoint® Accessibility Checker to verify PowerPoint® presentations are accessible (http://office.microsoft.com/en-us/powerpoint-help/check-for-accessibility-issues-HA010369192.aspx)
Graphics Usage	Provide a text description for images included on the page. Use an alt tag, which provides the opportunity to offer a short description in the HTML code (http://teach.ucf.edu/resources/document-formatting-guidelines/images/#about). If an alt tag does not provide enough characters to describe a picture, then use a long description in the HTML code. For the technically savvy, you can incorporate a span class using CSS and HTML to hide the text from the page visually. However, a screen reader will read the *hidden* content. The class' attribute would look like this: .hidden {position: absolute; left: -9999px;}
Audio/Video Usage	Provide users with either open or closed captioning. Open captioning is when captions are on all of the time and there is no ability to turn them off. Closed captioning allows the user control of turning the captions on and off. Search for video that has closed captioning. Ask companies to add closed captioning to their video products. If the instructor does not have copyright permission to add captions, provide a video transcript. Provide scene descriptions so that someone unable to see the content may know what's occurring onscreen.

TRENDS IN DISTANCE LEARNING

As distance learning continues to evolve so do the trends that will influence its future. Some of the most current trends in distance learning, such as mobile devices, HTML5 used in web and mobile application development, Massive Open Online Courses (MOOCs), and the proliferation of companies offering adaptive learning options, are discussed below.

Mobile Devices

The increased use of mobile devices by both students and instructors, especially in higher education, is affecting user's access in positive ways. These devices are portable, personalized with data and settings, and allow free or relatively inexpensive applications, especially those related to traditional AT, to be incorporated into the device quickly and easily. Preferred applications for those who require AT are generally built in HTML5 and tend to be more naturally accessible for users, but not always. Each device or application must be evaluated on its own merits and it should not be assumed that it is accessible. Some of these devices have built-in hardware features that are also inherently accessibility features (e.g., GPS, speech-to-text, text-to-speech navigation). With these types of features now within the mainstream culture, technology improves faster as more individuals have the ability to test it. Furthermore, it has been noted that mobile devices' counterpart, desktops and laptops, have been experiencing a marked decline. According to the market research firm, IDC, "…smart phones and tablets carried the 'smart connected device' category to new highs, topping one billion units worldwide" (Nagel, 2013, p. 1). This means that certain devices are becoming more accessible especially when professionals and instructors know how to utilize these technologies.

HTML5

Currently an increase in the use of HTML5 marks some exciting changes in terms of design and previously inaccessible materials like those using Adobe Flash®. In particular, HTML5 along with Accessible Rich Internet Applications (ARIA) will contribute extensively to the future appearance of the Web, its ease of use, and overall accessibility for individuals with disabilities. HTML5 focuses on creating accessible multimedia by turning the browser into a media player. What's particularly interesting is that Google™ decided in August 2011 to no longer support legacy browsers in order to be able to create enriched media applications using HTML5 (Panchapakesan, 2011). A larger question looms regarding when HTML5 will see full implementation. In the meantime, HTML5 promises to make content consistent without requiring multiple plugins. The intent of ARIA is to increase the overall web accessibility for screen reader users. It identifies the areas of a web page to the screen reader user and explains what is being *seen* (e.g., the navigation, title, or content). These two technologies lend hope that media will become even more heavily integrated while making access universal to all, which is the principle mission of Universal Design for Learning (UDL). But with these two exciting developments, there's still much to be done in making content user-friendly and media enriched.

Massively Open Online Courses

Another trend in online learning provides access to anyone. Deriving its title from the gaming realm (i.e., "Massively Multiplayer Online Games"), Massively Open Online Courses, or MOOCs have seen a marked increase in availability on the Web. These courses invite users from anywhere in the world to participate in learning a particular topic regardless of their institution affiliation. Evolving from sites such as MIT's

Table 4. Online resources

Title	URL	Description
Accessibility Tips Page	http://teach.ucf.edu/resources/accessibility-tips/	This page is designed to help individuals create or modify online course components so they are accessible.
Access Technology Higher Education (ATHEN)	http://www.athenpro.org/	Access Technology Higher Education Network focuses on accessible learning technology in higher education.
Association on Higher Education and Disability (AHEAD)®	http://www.ahead.org	A professional association dedicated to ensuring that all individuals with disabilities have access to postsecondary education.
Assistive Technology Industry Association (ATIA)	http://www.atia.org/i4a/pages/index.cfm?pageid=1	A not-for-profit organization of those involved with manufacturing, selling and providing technology-based assistive devices and services.
Blended Learning Toolkit	http://blended.online.ucf.edu/	A free resource created by the University of Central Florida and the American Association of State Colleges and Universities; it provides best practices, models and research related to blended learning.
California University System, Chico	http://www.csuchico.edu/roi/the_rubric.shtml	This rubric includes six domains that can be used to evaluate online course instruction.
Center for Applied Special Technology (CAST)	http://www.cast.org	A non-profit organization that works to provide learning opportunities and practical applications of accessibility.
Center on Disabilities at California State University (C-SUN)	http://www.csun.edu/cod/conference/	Provides an avenue for practitioners to share knowledge and best practices in the field of AT.
Closing the Gap (CTG)	http://www.closingthegap.com/	Provides resources and training opportunities through the publishing of its magazine.
Equal Access to Software and Information (EASI)	http://people.rit.edu/easi/itd.htm	Home of the free, Information Technology and Disabilities E-Journal.
Educause	http://www.educause.edu/	A non-profit organization that promotes the use of information technology to advance higher education.
Faculty Focus	http://www.facultyfocus.com/	Provides effective teaching strategies for face-to-face and online teaching.
FETC	http://fetc.org/	An organization that explores integration of technology and teaching strategies for K-12 and higher education through its annual conference.
IDC	http://www.idc.com	Use the search terms, “Education” and “IT” and you can track future trends.
National Federation for the Blind	https://nfb.org/	Advocating for blind individuals, the organization’s goal is to educate everyone with how to accommodate those who are blind by providing training, education and technology.
Quality Matters Program	https://www.qualitymatters.org/	A program created to assist faculty with designing a quality online program.

OpenCourseWare, where information was provided, but the teaching component was missing, MOOCs boast anywhere from 250 to thousands of users and today's MOOCs generally provide student-to-instructor interaction. A downside to taking one of these classes is the high levels of attrition rates; yet, the benefit to taking one can be far reaching. Most allow individuals the ability to access material for free, though some require students to purchase a textbook. Also, there is a large variety of courses available from some very credible institutions (e.g., Stanford). Individuals that successfully complete a MOOC may be able to apply this information towards promotions or other comparable rewards at their place of employment. Since college credit is generally not provided with the completion of a MOOC, a badge is sometimes awarded to indicate some level of proficiency or completion. As James Marshall Crotty (2012) of Forbes online magazine stated, "they are a free or low-cost way in which job-seekers can demonstrate hyper-specialized competency in lieu of, or as an adjunct to, a certificate or diploma" (p. 1). Some educational experts see MOOCs as an area of disruptive innovations, meaning "technology takes root in areas of nonconsumption – where the alternative is nothing at all" (Horn & Staker, 2011, p. 1). In many cases, MOOCs provide higher education courses to those who could not otherwise afford to do so.

No matter where MOOCs lead higher education, these courses should be created with accessibility in mind. When the institution falls under the premise of the Rehabilitation Act of 1973 or the ADA or both, any content including audio or video components will need to be adapted for accessibility as appropriate (Anastopoulus & Baer, 2013).

Flipped Classrooms

Another learning trend that bears discussing is what has been labeled, the "Flipped Classroom" (Goodwin & Miller, 2013). Based on the first tier of Bloom's Taxonomy of Learning (Kahn, 2012), this pedagogical style insists that mastery of information occurs in the online mode. According to this teaching premise, instructors provide basic knowledge and comprehension tasks online prior to the face-to-face meeting of the course. This is typically accomplished by taping a lecture and placing it into an online environment. In theory, watching the instructor's lecture prepares students to handle kinesthetic tasks in the classroom to further enrich learning. Originally designed to provide classroom information for students who were absent from class (Tucker, 2012), the flipped classroom optimizes the classroom-learning environment by ensuring that students are provided with material to review at their own pace with the ability to re-examine material as needed. This frees up the instructor to use classroom time to reinforce learning or tackle harder-to-grasp concepts. In the K-12 learning environment, taped lectures are provided online, there is commonly no decrease in the face-to-face learning time as there is in higher education (e.g., blended or hybrid courses). The idea is for the taped lectures to replace the assigned homework, and homework activities are discussed in the face-to-face setting. Care should be taken when implementing the use of taped lectures, and they should be used in conjunction with discussions and other types of activities whether online or in the face-to-face environment. Any taped lectures placed into an online environment will require captioning to accommodate students with hearing impairments. This is where lessons learned in the face-to-face and online environment become increasingly important for those who are aware of accessibility concerns.

Adaptive Learning

"Adaptive learning," also referred to as "computer-based learning" or "intelligent tutoring," is one last trend worthy of discussion. It is a concept based on the premise from the 1970s that predicted how computers would be used to create programs to provide interactive teaching opportunities for students (Dunn, 2012). Originally cost prohibitive, advances in computer technology, decreased overall computer costs, and advances in research in the area of student algorithm models has once again brought adaptive learning to the forefront (National Institute of Standards & Technology, 2005). It is being promoted as a way to provide students with a personalized learning environment. Many companies creating materials for adaptive learning provide personalized programs that *learn* how the student is progressing, which automatically increases or decreases the difficulty of the content and testing materials being provided. Adaptive learning collects detailed analytics and in some cases provides the flexibility to adapt student feedback within the courseware. Claims by companies piloting these products include better student retention, higher student satisfaction rates, and overall higher student scores. Other benefits to adaptive learning products may include a lower cost to students, single sign-on through the LMS, and the application of UDL in the design of the course materials (e.g., videos include captioning options). Distance learning has become the perfect medium for this concept and has the ability to meet the needs of today's diverse learners.

CONCLUSION

The focus of this chapter covered the history and definition of distance learning, types of distance learning interactions, and accessibility of online courses. Several trends affecting course delivery have also been discussed. Though many of the current issues related to managing and delivering distance learning were reviewed, there is still more work to be done in terms of ensuring access of online materials. This chapter has been designed to help guide instructors in creating accessible course materials for distance learning, understanding the landscape of today's learner, becoming familiar with the various types of LMS, and combating issues that could arise when these practices are not implemented. There have been dramatic improvements over the years by combining the developer's visions for new and improved technology and the end user experience.

Most of these trends support the overall status quo of education and some are purported to improve ease of access and learning outcomes. Who knows what other new developments and technologies are on the horizon. Keeping in mind that some technologies are considered as disruptive innovation, George Mehaffey, Vice President for Academic Leadership and Change at the American Association of State Colleges and Universities (2012), cautions those in education to learn to welcome and embrace change and "never be satisfied with the status quo" even though "following these rules will be more difficult" because "disruption happens most often to the unprepared." Accessibility will have to evolve as these new trends and disruptive technologies come to the forefront of education.

KEY TERMS AND DEFINITIONS

Accessible Rich Internet Applications (ARIA): Improves the way screen readers read information on the Internet to the user, thereby increasing overall web accessibility for screen reader users.

Cloud-Based: When digital information/data is stored somewhere on the Internet for someone else.

Hypertext Markup Language v5 (HTML5): The latest revision of HTML, the coding language that is used to present formatted content on the Internet.

Individuals with Disabilities Education Act (IDEA): As amended in 2004, this federal law is designed to make sure students with disabilities receive the following services: early intervention, special education, and any other related services.

Individualized Education Plan (IEP): Is a plan developed by a team of specialists assigned to a student with disabilities in the K-12 environment. The IEP has input by the parents and possibly the student. The plan must contain student objectives and it must be reviewed and updated each year by law (i.e., IDEA).

Job Access with Speech (JAWS®): A software program, called a screen reader, developed for personal computers that helps individuals who are blind or visually impaired read what is on the computer screen.

Proprietary Software: Also called closed source, refers to source code that is not open to the public, but instead must be changed, modified, or updated by the owner (business).

Screen Reader: Generic term for software that "reads" information presented on a computer screen to individuals who have a disability, such as a visual impairment or a learning disability.

Self-Hosted: Housing a software program or system (e.g., an LMS) in a special physical location or on specific hardware that is housed at the institution.

Chapter 27
Enterprise 2.0 in Engineering Curriculum

Andreas Ahrens
Wismar University of Applied Sciences, Germany

Olaf Bassus
Wismar University of Applied Sciences, Germany

Jeļena Zaščerinska
Centre for Education and Innovation Research, Latvia

ABSTRACT

Engineering education is facing a challenge to bring e-business closer to student engineers. Enterprise 2.0 application in engineering education advances engineering students' enterprise for the development of innovative products, processes, and services. The aim of the research is to analyze student engineers' Enterprise 2.0 application underpinning elaboration of pedagogical guidelines on student engineers' Enterprise 2.0 application in engineering curriculum. The meaning of key concepts of Enterprise 2.0 and engineering curriculum is studied. Moreover, the study indicates how the steps of the process are related following a logical chain: Enterprise 2.0 → engineering curriculum design → modelling Enterprise 2.0 application in engineering curriculum → empirical study within a multicultural environment. The present empirical research was conducted during the Baltic Summer School "Technical Informatics and Information Technology" in 2009, 2010, and 2011. The findings of the research allow drawing the conclusions that student engineers' Enterprise 2.0 application in engineering curriculum is efficient.

INTRODUCTION

Engineers succeed harder to find a job: engineer entering the service area has changed from working permanently at a large-scale enterprise to accepting project-related orders of large-scale enterprises by free engineers' office (Bassus, Wolfgramm, 2009, p. 38). Starting own business is a viable solution to overcome the unemployed or migrant status student engineers are exposed to.

Engineering curriculum is facing a challenge of Enterprise 2.0 application that brings e-business closer to student engineers and advances their enterprise.

DOI: 10.4018/978-1-4666-8246-7.ch027

Aim of the research is to analyze student engineers' Enterprise 2.0 application underpinning elaboration of pedagogical guidelines on student engineers' Enterprise 2.0 application in engineering curriculum.

The remaining part of this paper is structured as follows: The introductory background section demonstrates the authors' position on the topic of the research. The following part of the chapter involves five sections. Section 1 introduces theoretical framework on Enterprise 2.0 in engineering education. Research design is revealed in Section 2. The associated results of the empirical study are presented and interpreted in Section 3. Findings of the empirical study are analyzed in Section 4 followed by issues, controversies and their solutions. Afterwards, pedagogical guidelines on student engineers' Enterprise 2.0 application in engineering curriculum are given. Finally, some concluding remarks and a short outlook on interesting topics for further work are elaborated.

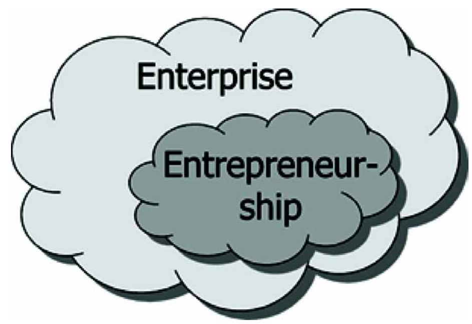
BACKGROUND

The conceptual framework of the present research is based on the approach to enterprise considered in a broader social context than within business framework only (Oganisjana & Koke, 2008, p. 225). Therein, the term *enterprise* involves *entrepreneurship* as shown in Figure 1 (Zaščerinska, Ahrens, & Bassus, 2011, p. 475).

Enterprise is defined as an individual complex capability to identify, generate and realize new socially valuable opportunities in the personal, professional, cultural, economic and other contexts of the social life (Oganisjana & Koke, 2008, p. 225).

The methodological background of the present research is based on System-Constructivist Theory. System-Constructivist Theory and, consequently, System-Constructivist Approach to learning introduced by Reich (Reich, 2005) emphasize that human being's point of view depends on the subjective aspect:

Figure 1. The relationship between enterprise and entrepreneurship



- Everyone has his/her own system of external and internal perspectives that is a complex open system and
- Experience plays the central role in the knowledge construction process (Maslo, 2007, p. 39).

MAIN FOCUS OF THE CHAPTER

Theoretical Framework

The theoretical framework of the present contribution involves the meaning of the key concepts of *Enterprise 2.0* and *engineering curriculum design* studied.

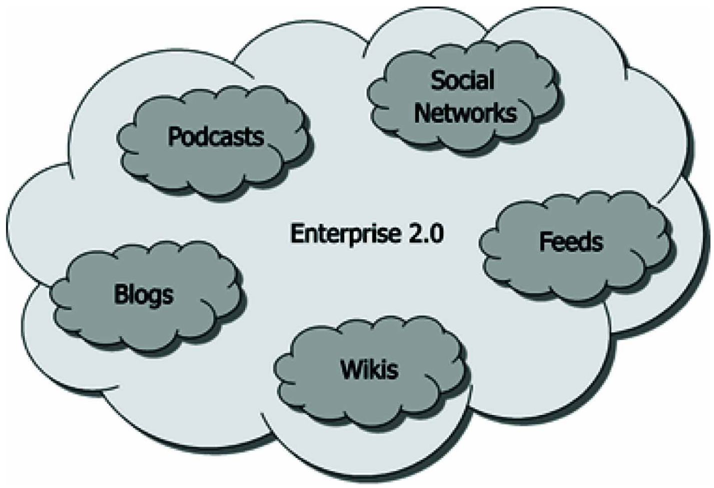
Enterprise 2.0 Definition

The present research is based on a widely accepted conception of Enterprise 2.0 as use of Web technologies for enterprise (business) purposes (Bassus, Ahrens, & Zaščerinska, 2011, p. 376).

Typical Enterprise 2.0 includes corporate blogs, wikis, feeds, and podcasts (Vossen, 2009, p. 38) as shown in Figure 2.

Blogs are a common way to stay in touch with customers, to inform about new products and to receive immediate feedback; they can also be used internally in order to discuss specific topics among the staff of an enterprise, in particular if people

Figure 2. Elements of Enterprise 2.0



are geographically distributed (Vossen, 2009, p. 38). Blogs allow a moderated interaction between participants, be it customers or colleagues, and a simple and efficient distribution of announcements, experiences, opinions, reports, or evaluations. A blog is useless without regular updates, a reasonable number of readers, continuous moderation, and good content. It is also a good idea for a company to treat independent bloggers just like regular journalists, since they might have a considerable readership. In order to stay up-to-date with a company blog, but also with other information an enterprise might publish, there are essentially two approaches: pull and push. The active or pull way is to read the information at my own liberty and pace; in the passive or push approach, the information will be delivered to me automatically.

A podcast is a particular form of feed consisting of audio or video material (Vossen, 2009, p. 38).

Wikis allow collaborative work on a common set of documents by many authors, and have been discovered as a new way of performing knowledge management in a learning organization.

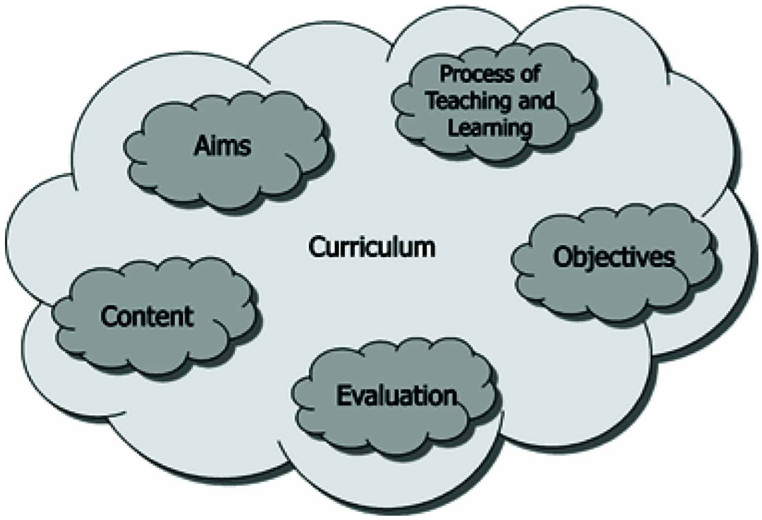
Online networks bring a dimension to the Web that goes beyond simple links between pages; they add links between people, between communities (Vossen, 2009, p. 38) and between organizations.

A network on the Web is typically the result of employing some software that is intended to focus on building an online community and, consequently, organization for a specific purpose (Vossen, 2009, p. 38). Social networks connect people with common interests and may be as simple as a blog, or as complex as Facebook or MySpace for mostly private applications, as LinkedIn or Xing for professional applications, or as Twitter for both. Another impact is that a social network may open up novel sources of revenue, in particular through advertising. Finally, Vossen (Vossen, 2009, p. 38) underlines that technology enables functionality, which as a "byproduct" leads to data collections, and users have a new tendency to socialize over the Web, by exploiting that functionality and the technology.

Engineering Curriculum Design

The search for an engineering curriculum design reveals the interaction of synonyms of the term *curriculum*, namely, *approach, plan* (often in Germany and Russia), *design*, *way of thinking,* as well as *strategy* and *programme* (Bassus, Zaščerinska, & Ahrens, 2011, p. 84).

Figure 3. Curriculum components

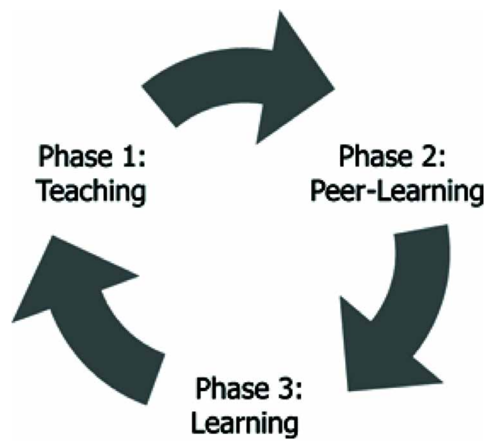


The present contribution considers curriculum as a central, organizing stance (Portelli & Vilbert, 2002a, p. 39). Curriculum comprises the following components: aim, objectives, content, process of teaching and learning as well as evaluation as depicted in Figure 3.

Curriculum based on System-Constructivist Approach to learning centres on possibilities for the co-construction and co-production of enterprise innovation, rather than on enterprise innovation as simply manager transmitted or simply employee created (Portelli & Vilbert, 2002a, p. 39). Therein, curriculum is centred on the process design (Philippou, 2005, p. 357). Moreover, the curriculum paradigm changes from an input based teaching/learning process to an outcome based process (Bluma, 2008, p. 673). Hence, the curriculum demonstrates how the learning outcomes are to be achieved by determining the phases of the process of teaching and learning: from teaching in Phase 1 to learning in Phase 3 through peer-learning in Phase 2 as depicted in Figure 4. Consequently, the present curriculum is regarded as peer-centred.

The stages of engineering curriculum design include the following steps (Boev, et al., 2011, pp. 41-42):

Figure 4. Phases of the process of teaching and learning



1. Curriculum conception (a brief description of the curriculum) that is aimed at identifying the curriculum constituencies and creation of the system ensuring the interaction with constituencies and studying of their needs.
2. Determination of curriculum educational objectives that are based on the needs of the constituencies. The curriculum objectives should be consistent with the mission of the institution to ensure its market competitiveness and demand of constituencies.

3. Definition of measurable curriculum learning outcomes, namely, knowledge, skills, and attitudes, which a student acquires during his study within the curriculum. The curriculum learning outcomes should correspond with the needs of the constituencies and ensure the achievement of the programme objectives by the graduates.
4. The curriculum design that demonstrates how the learning outcomes are to be achieved by defining the curriculum modules that ensure their achievement and by assigning European Credit Transfer and Accumulation System (ECTS) to learning outcomes. Each module has a number of learning outcomes that have their credit value depending on their contribution to achievement of programme outcomes. An educator responsible for a module must ensure development of its syllabus, teaching technologies, and supporting facilities aiming at achievement of module learning outcomes. Each module must have the assessment methods and tools for achievement of planned learning outcomes. The credits should not be assigned to a module if module does not include assessment of outcomes to be achieved. The notional learning time for a module is defined in accordance with its credit value.
5. Development of the assessment system for achievement of learning outcomes and curriculum objectives that should be done systematically and used for curriculum continuous improvement. The professional accreditation of curriculum by the accrediting agency is an important part of the assessment system of an institution.

Modelling Enterprise 2.0 Application in Engineering Curriculum

Theoretical analysis and empirical findings (Bassus, Zaščerinska, & Ahrens, 2011; Zaščerinska, Ahrens, & Bassus, 2011; Ahrens & Zaščerinska, 2011; Bassus, Ahrens, & Zaščerinska, 2011) allow modelling Enterprise 2.0 application in engineering curriculum as following:

1. Enterprise 2.0 application in engineering curriculum is conceptualized as promoting student engineers' self-confidence and capability to cope with their own problems in all spheres of life in a knowledgeable and enterprising way (Oganisjana & Koke, 2008, p. 225).
2. Educational objective of Enterprise 2.0 application in engineering curriculum is determined as to actively involve the student engineers in the life of Enterprise 2.0 (Portelli & Vilbert, 2002b, p. 15) by providing innovative opportunities and organizing student engineers' cognitive activity (Ahrens & Zaščerinska, 2011, p. 314).
3. Measurable learning outcomes are defined as
    a. Student engineers' knowledge of the Enterprise 2.0 concept,
    b. Student engineers' skills to use Enterprise 2.0 for their individual, organizational and professional purposes. It should be mentioned that by individual purposes private use of Enterprise 2.0 is meant: business functions are used within the family and friends. By organizational purposes use of Enterprise 2.0 between the colleagues is determined: business is made between the participants within the enterprise. And by professional purposes Enterprise 2.0 is used for business with the partners of the enterprise (Zaščerinska, Ahrens, & Bassus, 2011, p. 478).
    c. Student engineers' attitude towards participation in activities for their professional development such as education, in-service training and/or learning.

4. Enterprise 2.0 application is implemented in the Web 2.0 module of engineering curriculum (Ahrens & Zaščerinska, 2011, p. 316). The Web 2.0 module examines the advantages and problems of this technology such as architecture and management, protocol design, and programming, which makes new social communication forms possible. The Web 2.0 module does not reveal the concept of Enterprise 2.0. However, the Web 2.0 module comprises Enterprise 2.0 technologies (Ahrens & Zaščerinska, 2011, p. 316). The Web 2.0 module is assigned to 1 credit relevant to the European Credit Transfer System (ECTS). The teaching technology proceeds as following (Ahrens & Zaščerinska, 2011, p. 314-315):
    a. Phase 1 Teaching of Enterprise 2.0 application is aimed at a safe environment for all the students considering the essence of constructive social interaction and its organizational regulation. The present phase of Enterprise 2.0 application is organized in a frontal way involving the students to participate.
    b. Phase 2 Peer-Learning of Enterprise 2.0 application is designed for the students' analysis of an open professional problem situation and their search for a solution. The present phase of Enterprise 2.0 application involves the students to act in peers. A variety of teaching/learning activities with use of Enterprise 2.0 is provided by role plays, simulations, dialogues, prepared talks, discussions, and communication games and information-gap activities (Zaščerinska, 2009).
    c. Phase 3 Learning of Enterprise 2.0 application emphasizes the students' self-regulation with use of assessment of the process and self-evaluation of the results. The students present their self-evaluation by the end of each class.
5. The assessment system for achievement of learning outcomes and curriculum objectives comprises student engineers' self-evaluation, internal evaluation, and external evaluation (Hahele, 2005).

Research Design

The research design comprises the purpose and question, sample and methodology of the present empirical study to be considered.

Research Purpose and Question

The present empirical study was conducted during student engineers' Enterprise 2.0 application in the engineering curriculum of Baltic Summer School *Technical Informatics and Information Technology* to examine the efficiency of Enterprise 2.0 application in engineering curriculum. The research question is as follows: Has student engineers' Enterprise 2.0 application been efficient?

Sample of the Research

The present research conducted during the Baltic Summer School „Technical Informatics and Information Technology" in 2009, 2010 and 2011 involves 85 respondents, namely,

- 22 participants of Fifth Baltic Summer School, August 7-22, 2009, Tartu, Estonia,
- 28 participants of Sixth Baltic Summer School, August 13-28, 2010, Kaunas, Lithuania,
- 24 participants of Seventh Baltic Summer, August 12-27, 2011, Riga, Latvia,
- an educator of Baltic Summer School and
- 10 researchers in the field of educational research from different countries.

All the participants of Baltic Summer School *Technical Informatics and Information Technology* have got Bachelor or Master Degree in different fields of Computer Sciences and working experience in different fields related to computing and information technology.

The participants of Baltic Summer School *Technical Informatics and Information Technology* are with different cultural background and diverse educational approaches from different countries, namely, Latvia, Lithuania, Estonia, Russia, Belarus, Mongolia, Egypt, Germany, Pakistan, Indonesia, Great Britain, China, India, Nigeria, Romania and Mexico, etc. Hence, the sample is multicultural as the respondents with different cultural backgrounds and diverse educational approaches were chosen. Hence, the group's socio-cultural context (age, field of study and work, mother tongue, etc.) is heterogeneous.

Research Methodology

Interpretative research paradigm which corresponds to the nature of humanistic pedagogy (Lūka, 2008, p. 52) has been determined. Interpretative paradigm is characterized by the researchers' practical interest in the research question (Cohen, Manion, et al., 2003).

The qualitative evaluation research aimed at examining the efficiency of Enterprise 2.0 application has been used in the study (Kardoff, 2004, p. 137; Flick, 2004, p. 149).

Therein, efficiency involves quality and effectiveness as depicted in Figure 5 (Zaščerinska & Ahrens, 2011).

Figure 5. Elements of efficiency

Quality of Enterprise 2.0 application is regarded as the improvement of student engineers' knowledge, skills and attitudes (Zaščerinska, 2011a, p. 125). In its turn, effectiveness is considered as the educator's contribution to the student engineers' knowledge, skills and attitudes in Enterprise 2.0 application (Zaščerinska, 2011a, p. 125-126).

Enterprise 2.0 application is efficient if the inputs (Enterprise 2.0 application) produce the maximum output (students' knowledge, skills and attitudes (Zaščerinska, 2010b, p. 3) (Commission of the European Communities, 2006, p. 2). Therein, students' knowledge, skills and attitudes are the outcome criterion of efficiency of Enterprise 2.0 application (Zaščerinska, 2010b, p. 3).

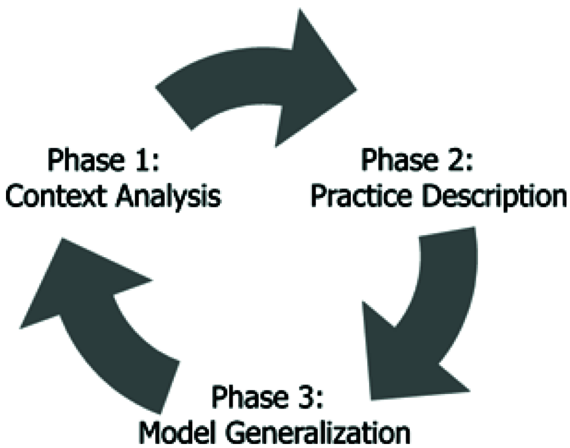
Figure 5 shows how the qualitative evaluation research proceeds (Zaščerinska, 2011a, p. 109)

- From the phase of exploration of the context analysis aimed at determining the present situation of Enterprise 2.0 application in promoting students' motivation and their readiness to implement the joint activity,
- Through the description of the practice that analyzes differences in levels of features researched and
- To the phase of generalization of the model that evaluates whether or not Enterprise 2.0 application is efficient for the development of students' knowledge, skills and attitudes (see Figure 6).

The qualitatively oriented research allows the construction of only few cases (Mayring, 2007, p. 1). Moreover, the cases themselves are not of interest, only the conclusions and transfers we can draw from this material (Mayring, 2007, p. 6).

Selecting the cases for the case study comprises use of information-oriented sampling, as opposed to random sampling (Flyvbjerg, 2006, p. 229). This is because an average case is often not the richest in information. In addition, it is

Figure 6. Phases of qualitative evaluation research



often more important to clarify the deeper causes behind a given problem and its consequences than to describe the symptoms of the problem and how frequently they occur (Flyvbjerg, 2006, p. 229).

Educator Contribution to Engineering Students' Learning Outcomes

The present part of the empirical study reveals analysis of engineering students' learning outcomes in Enterprise 2.0 application within Baltic Summer School *Technical Informatics and Information Technology* in 2009, 2010, and 2011 through thorough analysis of two surveys of the student engineers' feedback regarding their needs before and after educators' contribution.

Pre-Survey

In 2009 analysis of the students' feedback regarding their needs in Enterprise 2.0 application in the pre—and post-survey was based on the following questionnaire:

- **Question 1:** Do you know the word Web 2.0?
- **Question 2:** Do you know the basic idea of Web 2.0?
- **Question 3:** Have you already used Web 2.0, namely, Facebook, Twitter, Wikipedia, etc.?
- **Question 4:** Do you think Web 2.0 requires a lot of profound knowledge, namely, math, physics, etc.?
- **Question 5:** Do you think Web 2.0 is useful for your individual needs?
- **Question 6:** Do you think Web 2.0 is useful for your organizational use?
- **Question 7:** Do you think Web 2.0 is useful for your professional use?

It should be mentioned that needs analysis of three levels, namely, individual, organizational and professional, serves as an indicator of Enterprise 2.0 application in engineering education (Zaščerinska, Ahrens, & Bassus, 2011, p. 482).

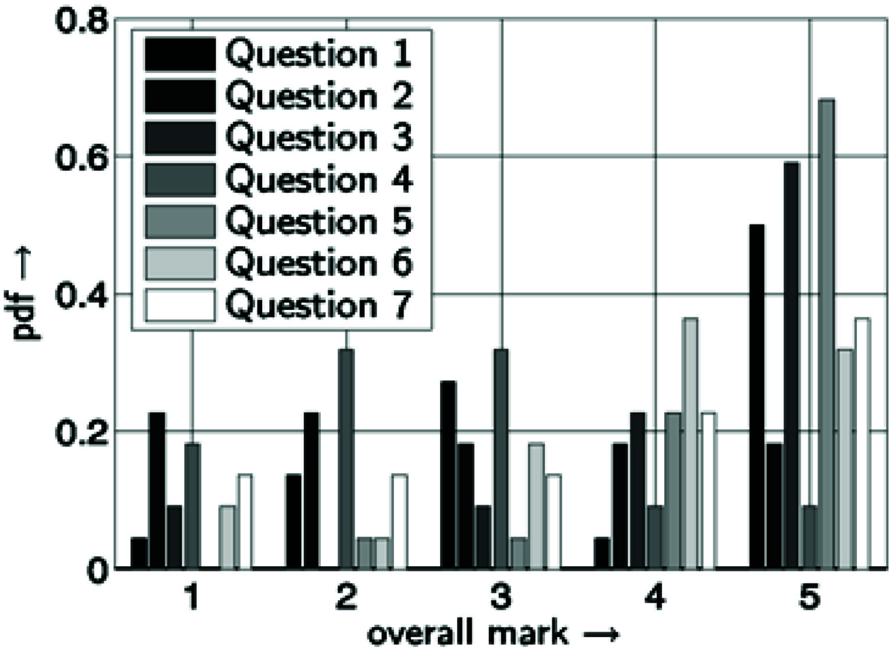
The evaluation scale of five levels for each question is given where "1" means "disagree" and low level of experience (knowledge, skills and attitudes (Zaščerinska, 2010a, p. 415) in Enterprise 2.0 application and "5" points out "agree" and high level of experience in Enterprise 2.0 application.

Analysis of the pre-survey, as depicted in Figure 7, carried out with 22 participants of Fifth Baltic Summer School, shows that the student engineers' Enterprise 2.0 application is heterogeneous as well as the student engineers do not know the possibilities offered by Web 2.0 properly.

In 2010 analysis of the students' feedback regarding their needs in Enterprise 2.0 application in the pre—and post-survey was based on the following questionnaire:

- **Question 1:** Do you know the concept of Enterprise 2.0?
- **Question 2:** Do you use Enterprise 2.0 for your individual purposes?
- **Question 3:** Do you use Enterprise 2.0 for your organizational purposes?

Figure 7. PDF (probability density function) of the pre-survey on August 7, 2009



- **Question 4:** Do you use Enterprise 2.0 for your professional purposes?
- **Question 5:** Do you participate in activities for your professional development, namely, education, in-service training, and/or learning, in use of Enterprise 2.0?

The evaluation scale of five levels for each question is given where "1" means "disagree" and low level of experience in Enterprise 2.0 application and "5" points out "agree" and high level of Enterprise 2.0 application.

Results of the pre-survey reveal that the student engineers do not realize the possibilities offered by Enterprise 2.0 properly.

In 2011 analysis of the students' feedback regarding their needs in Enterprise 2.0 application in the pre—and post-survey was based on the following questionnaire:

- **Question 1:** Do you have your own business and / or enterprise? The evaluation scale of two levels for the question is given where "1" means "no" and "2" - "yes."
- **Question 2:** Do you plan to start your own business and / or enterprise? The evaluation scale of two levels for the question is given where "1" means "no" and "2" - "yes."
- **Question 3:** To which extent do modern business and enterprise employ Web technologies? The evaluation scale of five levels for the question is given where "0-20%" means a low level of experience in Enterprise 2.0 application and "80-100%" points out a high level of Enterprise 2.0 application.
- **Question 4:** Please, indicate at least 3 Web technologies used by business and / or enterprise for business applications (up to five). The evaluation scale of five levels for the question is pointed out. 1 point is given for each correct answer thereby "1" means a low level of experience in Enterprise 2.0 application and "5" - a high level of Enterprise 2.0 application.

Results of the pre-survey reveal that the student engineers do not realize the possibilities for business offered by Enterprise 2.0 properly:

- One engineering student has got his/her own business,
- 11 engineering students plan to start their own business and / or enterprise,
- Nine engineering students consider that modern business employs Web technologies to 40-60%, 10 student engineers – 60-80% and five engineering students – 80-100%.
- Four student engineers indicated no Web technologies used by business, two engineering students - one Web technology used by business, three engineering students – two Web technologies used by business, 14 student engineers – three Web technologies used by business and one engineering student – four Web technologies used by business.

This is a reason why a support system to contribute to students' learning outcomes in a multicultural study's context was elaborated. This support system differs from the one offered in the special module of Web 2.0 by other educators as the proposed support system proceeds in a certain sequence.

Educator Contribution

Baltic Summer School *Technical Informatics and Information Technology* has been held in the Baltic States since 2005. The goal of studies in the Baltic Summer School is to prepare the student for international Master and Ph.D. programs in Germany, further specialization in computer science and information technology or other related fields, and learning in a simulated environment.

The Baltic Summer School contains a special module on Web 2.0 where Enterprise 2.0 is part. The process of teaching and learning was implemented in a certain sequence as following:

Phase 1 *Teaching* of Enterprise 2.0 application: The *Preparing a Good Introduction to a Presentation* information-gap activity (Buckmaster, 2004, p. 1) was analyzed in details. The student engineers' ability to make presentations for academic purposes in English is one of the expected results in the Web 2.0 module. The *Preparing a Good Introduction to a Presentation* information-gap activity is aimed at specialized training in Enterprise 2.0 application. The preparatory phase of Enterprise 2.0 application includes e-mailing the student engineers the task. The *Preparing a Good Introduction to a Presentation* information-gap activity comprised the following procedure:

Stage 1 was aimed at asking the student engineers to read out the task and at discussing the task in the whole group. There were no difficulties to understand the task because the student engineers did similar exercises.

Stage 2 assumed the student engineers to implement the task individually and/or in peers. If necessary, they applied Enterprise 2.0: the Web 2.0 module was hold in a computer classroom with the Internet connection available. The student engineers shared the Enteprise 2.0 resources available with pleasure.

Stage 3 dealt with sharing the student engineers' experience in reordering and completing the sentences with the group's participants. The student engineers managed to complete the sentences without any difficulty. However, the sentence order was given by the student engineers in a variety of combinations.

Stage 4 was designed to compare the engineering student dicoveries with the findings of other students. All the student engineers were helpful and friendly during the present stage of the studies: if there was a difficulty to find an idea on reordering the sentences, expression or word, the student engineers could get the necessary assistance from the groupmates and the educator. The observation revealed that word order contained some difficulties for the particular student engineers.

Stage 5 was devoted to re-completing the task by each student in the classroom. It was carried out by the engineering students with an interest: the student engineers re-asked some questions.

Phase 2 *Peer-Learning* of Enterprise 2.0 application**:** The prepared talk on the topic of the student engineers' master thesis was analyzed in details. The prepared talk on the topic of the students' master thesis is aimed at specialized training in searching for information with Enterprise 2.0 application. The preparatory stage included

- E-mailing the student engineers the task to prepare a presentation in English on the topic of the students' master theses,
- Clarifying whether the engineering students are able to work with the PowerPoint programme,
- A class with the emphasis on making a successful presentation for academic purposes in English that involves discussion on the presentation aims, its structure, materials, its procedure, use of the PowerPoint programme.

The prepared talk on the topic of the engineering students' master theses comprised the following procedure:

Stage 1 was aimed at a student engineer's presentation to his/her groupmates about his/her master thesis with Enterprise 2.0 application and the PowerPoint programme. The student engineers assisted each other in the technical area of presenting with use of the PowerPoint programme if there were some problems with the technical equipment, namely,

- New version of the PowerPoint programme of the student's presentation was not suitable to the PowerPoint programme available in the computer classroom,
- Transferring the presentation from the students' flash to the desktop of the computer, etc.,
- Opening the presentation files saved in the programmes different from the programmes available in the classroom, and
- Re-connecting the projector from the classroom computer to a private computer, etc.

Stage 2 engaged the students to switch the roles of speakers and listeners and to repeat the activity.

Stage 3 was devoted to the discussion on the student engineers' presentations. The discussion revealed that the engineering students while futher practising a presentation would take into consideration

- Pronunciation of academic terminology: the engineering students know how to spell the term, however, they do not pay a lot of attention to its pronunciation,
- Time limit for academic presentation, namely, 10 minutes in the Web 2.0 module, whereas the students' presentations took 15-20 minutes,
- Slide limit for academic presentation: there were 10 slides set as a requirement whereas the engineering students prepared 12-25 slides to emphasize the significance of the content of their master theses,
- To put only key words or phrases on a slide, not the whole sentence or text,
- Non-verbal aspects of communication:
  - The engineering students' location and distance within the public zone while making a presentation whereas some of the presenting students were standing at a classroom's wall,
  - To vary the pace and pitch of his/her voice,
  - Irritating nervous habits such as running his/her fingers through his/her hair or clicking the fingers or a pen, etc,
  - Not to turn his/her back on the audience in order to read the text of the presentation from the screen on the wall,

- Not to cross his/her arms and
- To look into each other's eyes,

- To bring an answer to a question subsequently if there is no possibility to reply immediately: for example, the presentation took a longer time than it was suggested.

Phase 3 *Learning* of Enterprise 2.0 application: The student engineers presented their self-evaluation. Self-evaluation comprised three questions as following:

1. What is your attitude to the Enterprise 2.0 application today?
2. What have you learned in the Enterprise 2.0 application?
3. How can you apply this knowledge in your academic field?

The present phase of English studies for academic purposes was organized in an individual way.

The students revealed their willingness to share their experience obtained in the classroom by the end of each class. Moreover, the students emphasized the importance of the possibility (Ilyinska, 2004, p. 92-93, 95)

- To see things from different perspectives,
- To produce a new organisation of familiar components and
- To consider new ideas by making connections among the olds.

Phase 3 *Learning* of Enterprise 2.0 application identified the most successful teaching and learning methods as demonstrated in Table 1 in order to improve the engineering students' learning outcomes.

Post-Survey

In 2009, analysis of the post-survey carried out in the Fifth Baltic Summer School on August 11, 2009 reveals that the participants' Enterprise 2.0

Table 1. Phases of Enterprise 2.0 application and their most successful teaching and learning methods

Phase	Most successful teaching and learning methods
Phase 1 Teaching Phase	communication games, information-gap activities
Phase 2 Peer-Learning Phase	Dialogue, role play, discussion, simulation: - conference and video-conference, - debate, - seminar and - project; prepared talk
Phase 3 Learning Phase	self-evaluation

application has become homogeneous and the participants have put the emphasis on Enterprise 2.0 application for professional needs as shown in Figure 8.

In 2010, results of the post-survey demonstrate the positive changes in comparison with the pre-survey:

- The level of the participants' experience in terms of knowledge of the concept of Enterprise 2.0 has been enriched,
- The level of the participants' experience in Enterprise 2.0 application for individual needs, for organizational and professional needs increased and
- The level of the participants' experience in terms of participation in activities for professional development such as education, in-service training and/or learning has been improved.

In 2011, results of the post-survey demonstrate the positive changes in comparison with the pre-survey:

- The number of engineering students who plan to start their own business increased from 11 to 16.
- The number of student engineers who considered that modern business employs Web technologies to 40-60% decreased from nine to five, 60-80% – decreased from 10 to nine and 80-100% – increased from five to 10 engineering students.
- The number of engineering students who indicated one or no Web technologies used by business decreased from six student engineers to five, two Web technologies used by business – decreased from three engineering student to one, three Web technologies used by business – increased from 14 student engineers to 15 and four Web technologies used by business – increased from one engineering student to three.
- The number of students who has got his/her own business remained steady – one engineering student.

Findings of the Research

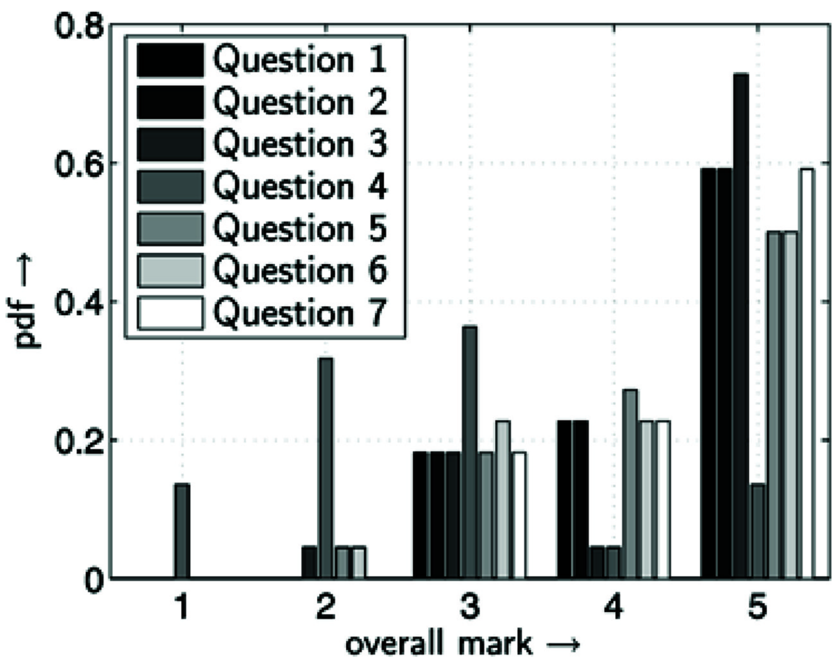
The present part reveals analysis of the research results in Enterprise 2.0 application within Baltic Summer School *Technical Informatics and Information Technology* in 2009, 2010, and 2011 through thorough analysis of student engineers' self-evaluation, internal and external evaluation.

Analysis of Students' Self-Evaluation of the Research Results

In 2010, in order to find out how each student's learning outcomes changed after Enterprise 2.0 application, analysis of the engineering students' self-evaluation comprised the structured interviews of three questions, namely,

1. What is your attitude to the Enterprise 2.0 application today?
2. What have you learned in the Enterprise 2.0 application?

Figure 8. PDF (probability density function) of the post-survey on August 11, 2009



3. How can you apply this knowledge in your academic field?

The aim of the interviews was to reveal the engineering students' evaluation of Enterprise 2.0 application for the development of student engineers' learning outcomes.

Comparing the answers of those 28 engineering students in the sample, the structured interviews were focused on the engineering students' positive experience in Enterprise 2.0 application. For example, a student reveals the inter-relationship between the positive experience of social interaction and cognitive activity in Enterprise 2.0 application:

I feel this class to be very useful to me because I am improving my knowledge in Enterprise 2.0 application.

The student evaluates her own learning process:

I think I like the Web 2.0 module, because I begin to understand how to apply Enterprise 2.0.

The summarizing content analysis (Mayring, 2004, p. 269) of the structured interviews demonstrates that Enterprise 2.0 application promotes the development of students' learning outcomes. Moreover, Enterprise 2.0 application contributes to the safe and friendly teaching/learning environment for all the participants and provides opportunities of constructive social interaction and cognitive activity.

Analysis of Internal Evaluation of the Research Results

Internal evaluation involves engineering students and educators of the educational establishment. Analysis of the internal evaluation of the engineering students' learning outcomes comprised the data processing, analysis, interpretation, and analysis of the results of the pre-survey and post-survey of the student engineers.

In order to determine the developmental dynamics of each student's learning outcome in 2010, comparison of the pre-survey and post-survey results was carried out.

The *Mean* results of the descriptive statistics highlighted in Table 2 demonstrate that the level of the students' Enterprise 2.0 application has increased in the post-survey (3.28) in comparison with the pre-survey (1.68).

The comparison of the *Standard Deviation* results as shown in Table 3 reveals that the scores of the post-survey are spread wider than the scores in the pre-survey.

The results of *Mean* and *Standard Deviation* within the surveys of the students' feedback regarding their needs in Enterprise 2.0 reveal that most of answers are concentrated around Level 2 and 3. Thus, there is a possibility to increase the students' use of Enterprise 2.0 within Web 2.0 technologies.

In order to determine the developmental dynamics of each student's learning outcome in 2011, comparison of the pre-survey and post-survey results was carried out.

The *Mean* results of the descriptive statistics highlighted in Table 4 demonstrate that the level of the students' Enterprise 2.0 application has increased in the post-survey (2.39) in comparison with the pre-survey (2.15).

Table 2. Mean analysis of the pre- and post-survey in 2010

Question	Pre-Survey	Post-Survey
1	1.86	3.25
2	1.75	3.44
3	1.54	3.33
4	1.57	3.16
5	1.68	3.21
mean	**1.68**	**3.28**

Table 3. Standard deviation analysis of the pre- and post-surveys in 2010

Question	Pre-Survey	Post-Survey
1	1.85	2.35
2	1.14	2.40
3	1.99	2.39
4	1.57	2.19
5	1.96	2.31
mean	**1.70**	**2.33**

Table 4. Mean analysis of the pre- and post-survey in 2011

Question	Pre-Survey	Post-Survey
1	1.04	1.04
2	1.46	1.66
3	3.83	4.21
4	2.25	2.66
mean	**2.15**	**2.39**

The results of *Mean* within the surveys of the students' feedback regarding their needs in Enterprise 2.0 reveal that most of answers are concentrated around Level 2. Thus, there is a possibility to increase the students' Enterprise 2.0 application within Web 2.0 technologies.

Hence, considering judgment to be part of the art of statistics (Gigenzer, 2004, p. 603), the conclusion has been drawn that Enterprise 2.0 application influenced the development of the engineering students' learning outcomes demonstrated by the difference between the levels of the student engineers' learning outcomes in the pre- and post-survey.

Analysis of External Evaluation of the Research Results

The external evaluation comprises 10 researchers from different countries. It should be mentioned that all the researchers participated in the external evaluation of the research results are professors in the fields connected with educational research.

The external evaluation of the research results comprised the non-structured interview of one question as following: What is the researcher's view on the present research on Enterprise 2.0 application for the development of engineering students' learning outcome? The aim of the non-structured interviews was to reveal the researchers' evaluation of Enterprise 2.0 application for the development of engineering students' learning outcome.

For example, a respondent considered the model of Enterprise 2.0 application for the development of engineering students' learning outcome to be a transformative methodology. The researcher stressed the following advantages of the model: focus of establishing a system, viewing the overall personality of the learner, the fact that educators can indeed change the typical classroom environment, the sequence of the implementation of the model, developing newer constructs that will truly help the student to internalize new material and the student having the "ability to create knowledge".

The summarizing content analysis (Mayring, 2004, p. 269) of the data reveals that the respondents evaluate Enterprise 2.0 application for the development of engineering students' learning outcome positively. Thus, the conclusion can be drawn that Enterprise 2.0 application enhances development of engineering students' learning outcome.

ISSUES, CONTROVERSIES, PROBLEMS

One of the Enterprise 2.0 issues is to consider the historical development of *Enterprise 2.0* and *Enterprise 2.0* in pedagogy.

Another point is the paradigm shift from socialization within Web 2.0 to peer contribution within Web 3.0 (Ahrens & Zaščerinska, 2011, p.

Table 5. Enterprise 2.0 in pedagogy in different historical periods

Phase	Historical Period	Approach	Elements of Enterprise	Educational settings
1.	2000 - 2006	Enterprise 1.0 as socialization	Social software	Tasks with use of Enterprise 1.0
2.	2006 - up to now	Enterprise 2.0 as community	Social software and online networks	Teaching techniques with use of Enterprise 2.0
3.	2007 - up to now	Enterprise 3.0 as organization	Online networks	Practice of the Enterprise 3.0 curriculum
4.	2010 - up to now	Enterprise 4.0 as society	Ambient intelligence, WebOS or Web operating system, artificial intelligence	University Degree

319) and growing need to quantify uncertainty with greater precision (Nadhan, 2008) that has already increased the significance in the Enterprise 2.0 institutionalization. However, Enterprise 2.0 is conceptualized but still not institutionalized (Nadhan, 2008).

SOLUTIONS AND RECOMMENDATIONS

Table 5 demonstrates that the study of *Enterprise 3.0* and *Enterprise 3.0* in pedagogy has not had a long story (Bassus, Ahrens, & Zaščerinska, 2011, p. 381).

Regarding the institutionalization of Enterprise 2.0, an attempt has led to the concept of Enterprise 3.0 defined as an agency based on the curriculum practice (Bassus, Zaščerinska, & Ahrens, 2011, p. 84).

FUTURE RESEARCH DIRECTIONS

Enterprise 3.0 demonstrates the technology of online networks to assemble and manage large communities with a common interest in peer contribution, where organisations and enterprises have made use of the potential of Web 3.0 with single solutions such as online networks. However, Enterprise 4.0 as shown in Table 5 will be derived from the full application of Web 4.0 concepts such as ambient intelligence, WebOS or Web operating system, artificial intelligence, rather than Web 3.0 point solutions (Bassus, Ahrens, & Zaščerinska, 2011, p. 381). This remains as an open point for the future. It should be mentioned that the concept of a Web operating system or WebOS is distinct from Internet operating systems. Web operating system or WebOS is independent of the traditional individual computer operating system.

Another direction of further research might include Enterprise 2.0 application in five phases (Zaščerinska, 2011b, p. 145):

- Teaching in Phase 1,
- Teaching with elements of peer-learning in Phase 2,
- Peer-learning in Phase 3,
- Peer-learning with elements of learning in Phase 4 and
- Learning in Phase 5.

CONCLUSION

The findings of the research allow drawing the conclusions that Enterprise 2.0 application is efficient for the enhancement of student engineers' learning outcomes.

Regarding quality assurance, it is evident that the student engineers' learning outcomes have been enriched. Therein, Enterprise 2.0 application has contributed to the development of the engineering students' learning outcomes.

Regarding effectiveness of the educator's contribution to the student engineers' learning outcomes, it is evident that the engineering students widened their experience in social interaction and cognitive activity with the Enterprise 2.0 application. The engineering students' attitude is positive. That shows that the studies influence the student engineers' learning outcomes.

Moreover, validity of the qualitative evaluation research has been provided by use of the mixed methods' approach to the data obtaining, processing, and analysis. Validity and reliability of the research results have been provided by involving other researchers into several stages of the conducted research. External validity has been revealed by international co-operation. Therein, the researchers' positive evaluation of Enterprise 2.0 application for the development of engineering students' learning outcomes validates the findings of the present research.

Thus it might be stressed that Enterprise 2.0 application is efficient if students' needs are met and a support system implemented in the phases of a certain sequence is designed that would secure their social experience in social interaction and cognitive activity.

The present research has *limitations*. The inter-connections between engineering students' learning outcomes, Enterprise 2.0 application, and the sequence of its implementation have been set. Another limitation is the empirical study conducted by involving educators and students at master level of one tertiary institution. Therein, the results of the study cannot be representative for the whole area. Nevertheless, the results of the research - definition of Enterprise 2.0, Enterprise 2.0 application and the qualitative evaluation research – may be used as a basis of the development of engineering students' learning outcomes at master level of other tertiary institutions.

The following pedagogical guidelines on Enterprise 2.0 application in engineering curricula are elaborated: Enterprise 2.0 application proceeds from Phase 1 *Teaching* aimed at determining the notion of constructive social interaction and its organizational regulation through Phase 2 *Peer-Learning* designed for the students' analysis of an open academic problem situation and their search for its solving that provide each student with the opportunity to construct his/her own social experience to Phase 3 *Learning* focused on the students' self-regulation with use of evaluation of the process and self-evaluation of the result.

KEY TERMS AND DEFINITIONS

Constituencies: Broad statements that describe what graduates are expected to attain within a few years of graduation.

Curriculum: A central, organizing stance (Portelli & Vilbert, 2002a, p. 39).

Effectiveness of Enterprise 2.0 Application: Educator's contribution to the student engineers' knowledge, skills and attitudes to Enterprise 2.0 application (Zaščerinska, 2011a, p. 125-126).

Enterprise 2.0: Use of Web technologies for enterprise (business) purposes.

Enterprise 3.0: An agency based on the curriculum practice (Bassus, Zaščerinska, & Ahrens, 2011, p. 84).

Experience: Knowledge, skills, and attitudes (Zaščerinska, 2010a, p. 415).

Learning Outcomes: Knowledge, skills, and attitudes.

Quality of Enterprise 2.0 Application: Improvement of students' knowledge, skills and attitudes (Zaščerinska, 2011a, p. 125).

Section 3
Frameworks and Methodologies

This section provides in-depth coverage of conceptual architecture frameworks to provide the reader with a comprehensive understanding of the emerging developments within the field of Curriculum Design and Classroom Management. Research fundamentals imperative to the understanding of developmental processes within Curriculum Design and Classroom Management are offered. From broad examinations to specific discussions on methodology, the research found within this section spans the discipline while offering detailed, specific discussions. From basic designs to abstract development, these chapters serve to expand the reaches of development and design technologies within the Curriculum Design and Classroom Management community. This section includes 16 contributions from researchers throughout the world on the topic of Curriculum Design and Classroom Management.

Chapter 28
Blended Course Design:
Where's the Pedagogy?

Patricia McGee
University of Texas at San Antonio, USA

ABSTRACT

Blended or hybrid course design is generally considered to involve a combination of online and classroom activities. However defining blended courses solely based on delivery mode suggests there is nothing more to a blended course than where students meet and how they use technology. Ultimately there is a risk that blended courses defined in this way will not utilize effective strategies that have proven to improve learning for students. This study investigates pedagogical strategies or designs that have reported success in higher education coursework as published in articles that address blended pedagogy. A qualitative meta-interpretive analysis identified eight themes: definitions of blended design, meetings for the learner, online priority, technology with a purpose, focused e-interactions, active learning, distribution of time, pedagogical chunking, and outliers and omissions.

INTRODUCTION

Blended or hybrid courses have been adopted by institutions of higher education as a strategy to reduce classroom use, increase learner engagement, and increase utilization of information technology (Snart, 2010). The US National Center for Academic Transformation (NCAT) set the standard for adoption of alternative course delivery models through course redesign models (see http://www.thencat.org/PlanRes/R2R_ModCrsRed.htm) yet the parameters of hybrid or blended courses are broad and the terms used interchangeably blurring the meaning. *Hybrid learning* typically refers to multiple and distinct instructional modes that combine to produce an instructional sequence. This might involve combinations of classroom lectures, online tutorials, workshops, research, etc. Such modes may be intentional or optional, selected by the learner or directed by the curriculum, and occur in multiple locations with or without the interaction of peers. *Blended learning* has come to mean a combination of face-to-face learning with technology-delivered experiences/instruction that are integrated so the learner experiences a 'blend' as opposed to isolated experiences in different modes but not connected. In this format students work in a classroom, or extend their work

DOI: 10.4018/978-1-4666-8246-7.ch028

online then return to the classroom closing a loop of interaction and learning. These experiences are 'blended' so that learning is connected and integrated by design. Hybrid courses segment learning experiences rather than integrate them as do blended courses. In this sense, hybrid courses are closer to NCAT's Supplemental Model of course design where little changes in the classroom and online experiences are extras rather than requirements.

It is the author's contention that blended courses offer an affordance not possible through classroom only, 100% online, or supplemental courses. What does a well-designed blended course look like? Do common features in blended courses exist? What is effective blended pedagogy? This study attempts to articulate those characteristics of blended courses that contribute to an effective pedagogical approach.

PEDAGOGICAL ORGANIZATION IN BLENDED COURSES

This study builds on the author's previous work regarding blended course "best" practices (McGee & Reis, 2012). Best practice guides for blended learning are readily available from different countries, various institutions, and from a variety of businesses. The term "best" implies only one way to accomplish something well, and that is not the case with blended pedagogy. Effective *practice* is a more accurate descriptor. McGee and Reis (2012) analyzed effective practices for blended course design and found while many research-based recommendations are available, there is little articulation of *pedagogical* strategies to inform course design. Without understanding the unique pedagogy of a blended courses, it is difficult to design. McGee and Reis (2012) use the following definition to better communicate the essential components of a blended design:

Blended course designs involve instructor and learners working together in mixed delivery modes, typically face-to-face and technology mediated, to accomplish learning outcomes that are pedagogically supported through assignments, activities, and assessments as appropriate for a given mode and which bridge course environments in a manner meaningful to the learner.

No clearly articulated *pedagogical* models exist to guide course design, in spite of reported success and student preference for the blended delivery mode. Picciano (2009) believes we know so little about this delivery system because there is no taxonomy or commonly accepted framework that provides a foundation for critical study. "One school's blended is another school's hybrid, or another school's mixed-mode" (p.8). The lack of a coherent framework based on effective practices contributes to the ill-defined nature of a blended course. The metaphor of hybrid car versus integrated power systems illustrates the dilemma. Turning 'on' one mode while another mode is 'off' may be efficient and effective, however, such an approach is essentially different from an approach where there is no discernable segregation between power systems. In a learning context, a hybrid approach may be effective and appropriate for some courses, but hybrid is essentially different from a blended approach.

Khan (2007) alludes to five pedagogical designs in his dimensions of the blend:

1. Blending offline and online learning;
2. Blending self-paced and live, collaborative learning;
3. Blended structured and unstructured learning;
4. Blending custom content with off-the-shelf content;
5. Blending learning, practice, and performance report (p. 7).

Each of Khan's designs offers insight into the breadth of possibilities and dilemmas when making decisions about blended course structures.

Much of the blended literature is anecdotal with a focus on instructor, program, or institutional reflections regarding the contributions/challenges of design and implementation. Research in this area concentrates on learner traits, grades, faculty/learner levels of satisfaction, and/or levels of learner engagement (see Dzuiban, Hartman, & Moskal, 2004; Nagal, 2009). There is evidence that utilizing a blended/hybrid course design impacts teaching and learning in different ways and thus offers other dimensions to the course design. As courses are re-designed so may instructors re-conceive their role and practices. Bonk and Graham (2005) propose the following categories of blends related to instructor shifts:

1. **Enabling Blends:** Enabling blends primarily focus on addressing issues of access and convenience. For example, blends that are intended to provide additional flexibility to the learners or blends that attempt to provide the same opportunities or learning experience but through a different modality;
2. **Enhancing Blends:** Enhancing blends allow for incremental changes to the pedagogy but do not radically change the way teaching and learning occurs. This can occur at both ends of the spectrum. For example, in a traditional F2F learning environment, additional resources and perhaps some supplementary materials may be included online. At the other end of the spectrum, a field-based course may allow students to interact with professionals and peers and get support online with few course meetings, but assignments and assessments remain unchanged;
3. **Transforming Blends:** Transforming blends are blends that allow for a radical transformation of the pedagogy. For example, a change from a model where learners are just receivers of information to a model where learners actively construct knowledge through dynamic interactions. These types of blends enable intellectual activity that was not practically possible without the technology. (Patel, 2006, p. 4)

An instructional integration of technology plays a key role in blended course delivery and potentially to academic success in general. Habley and McClanahan (2004) note instructional use of technology as number six of the fifteen factors contributing to student retention in general. Huang, Ma, and Zhang (2008) confirm virtual learning environments contribute to success, but they also claim the distribution of engagement and interaction improves, expands and individualizes learning. Norberg, Dzuiban, and Moskal (2011) found that geographical location does not define blended, however temporal space (Huang, Ma, & Shang, 2008) in which learners and instructor interact, creates a blended pedagogy by framing interactions in both synchronous and asynchronous settings.

The term pedagogy comes from the Greek words *paid* (child) and *agogus (leader of)*, which directly translated means *to lead the child*. Thus pedagogy is situated in guidance through direction towards a pre-determined end. Pedagogy is more commonly used in reference to the methods and practice of teaching (Oxford Dictionary). For the author, pedagogy is situated in instruction design to lead the student and therefore includes what students do in the classroom and online to facilitate learning. Understanding what learning and teaching looks like in this mode helps to clarify and provide strategies for the design of blended/hybrid courses.

Articulation of pedagogical organization varies in description (little to much detail) and scope (one course to academic programs). For example, there are high-level views focusing on a general approach to organizing the course. Chatfield (2010) found two distinct ways of organizing or layering blended courses described as *frontloading* and *backloading*. Frontloading requires students to be prepared to discuss and work through course content in face-to-face class meetings. Content is presented online. In a backloaded course, face-to-face meetings are used to introduce content and place it in context for the online work that students will complete before the next class meeting. The following examples are not exhaustive but representative of the range of pedagogical approaches in blended designs.

Some institutions approach blended organization with programmatic outcomes in mind. For example, the European Community (EC) incorporates soft skills from which both online and blended course design result in a dynamic and interactive learning environment. The EC defines soft skills as abilities to complete specific work related requirements, e.g., presentation of knowledge, effective web search, project work, teamwork, and problem solving (Kantrowitz, 2005). Each of these skills requires specific pedagogical approaches intended to assist skill acquisition through learner-driven activities. Thus, active learning is a core component in this soft skill approach with many possible variations.

Related to a skill-based approach is the Chinese instructional design model of using "knowledge points" (Wang, Novak, & Shen, 2008, p. 307), to clearly define content units or skills around which a course is designed. Unlike instructional objectives designed to articulate a demonstration of learning, knowledge points are to be remembered and recalled at any future point in time. For example, in a blended computer science course, after knowledge points have been presented in class, questions are delivered to students as a formative assessment. The instructor then provides real world problems related to knowledge points and students discuss through SMS. Therefore, this approach assists students' learning through iterative practice across learning environments to reinforce core learning.

Knowledge priorities are used as the focus of a game-based learning approach illustrated by Shang, Jong, Lee, and Lee (2008). In this strategy game-based learning is combined with traditional learning in three phases where the student proceeds through the following sequence:

Phase 1: Preliminary acquisition of some high-level knowledge in specific subject domains through teacher scaffolding;

Phase 2: Active participation as game characters participate in a virtual interactive environment to construct knowledge and skills through their near real-life game-play experiences;

Phase 3: Reflection and generalization of game-based learning through teachers' debriefing. Students write a reflection after every experience and each group submits a debriefing report (p. 348).

Starting in the classroom allows priorities to be set and the instructor to present core content and explain processes. The online activities of phases two and three are active and applied. Phase three brings learning full circle by connecting what they learned didactically to their virtual experience. Such an organization is somewhat formulaic while allowing modifications across level of course and discipline.

A community of practice (CoP) approach frames some models and can be illustrated by the Guangdong Radio and TV University (GDRTVU) offering online and blended instruction for 89 schools in the region (Le, 2008). GDRTVU describes blended learning as: "a combination of multiple elements including the learner's characters, delivery ways, learning theories, technologies, and other educational resources" (p. 295). Designers modify course organization based on what is known about their learners through a character system that analyzes "physiology, psychology, sociology, geography, ICT infrastructure, eLearning skill, learning behavior, learning favor, motive and wish, and the view on [open and distance learning] and learning materials" (p. 297). A CoP approach focuses on the nature of each group of learners that changes every time the course is offered. Learning materials are made available for self-directed learning: problem-based, context-based, or case-based. Some of these learning experiences are institutionally designed self-test exercises, and some are from the Internet. Thus, virtual communities of practice are formed with participation from teachers, instructional designers, technicians, tutors, and learners and utilize the following strategies to facilitate interaction:

1. Finding protagonists;
2. Encouraging all learners to participate interaction by formative assessment;
3. Making quick responses to learners;
4. Talking between teacher and learner equally;
5. Designing value discussion topic from their work experiences;
6. Trying problem-based group collaborative learning (p. 300).

While the aforementioned high-level approaches to pedagogy are not exhaustive, they do illustrate emerging design models being used to examine effective strategies. In a separate analysis being conducted at the same time as this study, the author has identified 17 models of blended learning indicating approaches to blended learning are as diverse as classroom-based instruction (Beatty, 2005, Carmen, 2002; Chan, Lam, Yang, Mark, & Leung, 2010; Chen, 2007; Garrison & Vaughn, 2008; Chew, Jones, & Turner, 2008; Huang, Ma, Zhang, 2008; Kerres & Witt, 2003; Lee & Dashew, 2011; Littlejohn & Pegler, 2007; Martyn, 2002; Norberg, Dziuban, & Moskal, 2011; Picciano, 2009; Salmon, 2004; Sankey, 2010; University of Wolverhampton, n.d.; Valiathan, 2002; Wong, 2008; Yukawa, 2010). Thus with so much potential variation, looking broadly across reports of blended pedagogy offers an opportunity to look for patterns from practice, rather than generic pedagogical models that may come solely from classroom or 100% online course models.

METHOD

This study investigates pedagogical strategies or designs reporting success in higher education coursework as published in articles about blended and hybrid pedagogy. Specifically the research identified pedagogical patterns among blended course designs. A meta-interpretive analysis (Weed, 2005) design was used to analyze patterns across literature. This approach is used when there is little or no basis for excluding data, when "meaning in context" can reveal insights, interpretation is the basis of understanding, and when iteration drives the analysis process. Because reports of blended course design are widespread (across disciplines, journals, and contexts) and methodology is varied (both quantitative and qualitative), with little specificity regarding pedagogy, quantitative meta-analysis is not possible. Also, it was difficult to predict what patterns could be expected, except from effective practices guides (McGee & Reis, 2012.) Therefore, the author entered into the research with the following inclusion criteria; reference to the pedagogical design and higher education courses at any level.

For this study *pedagogy* includes the intentional design of instruction informing what students do to learn, tools used to support learning, and activities facilitating learning. An initial review of literature indicated the study of pedagogical designs was not a research focus across cases. Much literature focuses on one or more of the following: satisfaction of the learner (Moskal, Dzuiban, & Hartman, 2010; Partridge, Ponting, & McKay, 2011; Precel, Eshet-Alkalai, & Alberton, 2009; Olapiriyakul & Scher, 2006), learner achievement through learning styles (Choi, Lee, & Kang, 2009), technology fit for delivery mode (Lidstone, & Shield, 2010) or a specific instructional strategy, such as discussion (Hwang & Arbaugh, 2009).

In order to broaden the base of pedagogical strategies used in blended courses, non-research literature was included. Identification of target literature from publications in both subscription-based and open journals was conducted using literature search tools including ProQuest™, ERIC™, and the Directory of Open Access Journals (DOAJ). Inclusion criterion was as follows: higher education only, any discipline, research-based, non-research reporting results, and non-research reporting pedagogy. By the end of the study, the collection of literature consisted of 74 articles: 48 undergraduate levels, 23 graduate level, and three with a focus on faculty development reporting pedagogical course designs. Institutional teams, non-academic units, academic units, and individual faculty members authored the articles. Because authorship may relate to instructional priority the author did not filter in order to determine if themes persisted regardless of lens or institutional role.

Literature collection was ongoing and reported practices were analyzed using a constant comparison method to identify similarities across reports (Patton, 1990.) Initially the author wrote general descriptions of pedagogy: what the learner did, what tools were used, and what activities were implemented. From these general descriptions, categories were determined, described, and finally labeled with a descriptive title describing the nature of the practice. While there are many reports of blended pedagogy across disciplines, the point of saturation was eventually reached when no new practices emerged from newly identified articles and at this point no further articles were collected.

Once categories were clearly described and the narrative written, the author reviewed and revised in order to reduce repetition and clarify findings for the sake of consistency, discrepancy, or omission. The findings are filtered through the author's work situated primarily in instructional design. Thus, the interpretation of pedagogical reports is focused on design rather than instruction, technological management, or learner perspectives.

FINDINGS

Findings of this study indicate blended pedagogy has breadth and variation, as well as consistent patterns. It is important to note while the reported themes overlap the subtleties among categories of findings are important in capturing blended pedagogy. For example, students working in teams may be doing so to debate, inquire, create a product or develop a project. Each of the pedagogical strategies may or may not take place in class or online. The reasons for implementing a strategy in one mode or the other can provide insight. Themes indicate what is present but also what is absent in reports. Why certain information is not reported cannot be known. However, the identification of patterns indicate what is important to instructors and thus a priority in the design of blended courses. Themes include: definitions of blended design, meetings for the learner, online priority, technology with a purpose, focused e-interactions, active learning, distribution of time, pedagogical chunking, and outliers and omissions.

DEFINITIONS

Even though it was clear that reports were about blended courses, many authors omitted a definition of blended; 30 of the 74 articles included no definition. Those authors stating definitions varied. Given the variability of definitions in effective practices (MacDonald, 2008; McGee & Reis, 2012) and across sectors (Khan, 2007) omitting a definition brings into question what exactly is being described. As noted in this paper, percentages of time segments in the classroom or online mode are often used to frame blended but they do not explain how differently courses are designed. Therefore a definition helps to clarify what a blended course is and is not.

Most included a standard definition of combined classroom and online interactions (Aitken, 2011; Amaral & Shank, 2010; Banerjee, 2011; Bergtrom, 2011; Bluic, Ellis, Goodyear, & Piggott, 2011; Boyd, 2008; Choi, Lee, & Kang, 2009; Clayton, Blumberg & Auld, 2010; Dawson, 2010; Gerbic, 2009; Lopez-Perez, Perez-Lopez, & Rodriguez-Ariza, 2010; Liu, Don, Chung, Lin, Chen & Liu, 2010; Huang & Arbaugh, 2006; Skibba, 2006; Olapiriyakul, & Sher, 2006; Precel, Eshet-Alkalai, & Alberton, 2009; Vaughn & Garrison, 2005). Several authors articulated *pedagogical* definitions: Adventure Learning (Doering, Miller & Vletsianos, 2008), Carpe Diem Intervention, Active/Participative Learning and Individualization (Armellini & Aiyegbayo, 2010; Huang, Ma, & Zhang, 2008). One definition was contextual referring to blended learning in a virtual world environment (Dreher, Reiners, Dreher & Dreher, 2009).

The focus on geographical location (classroom vs. online) may limit pedagogical designs not contingent upon space or the learner's needs. Little attention was given to what happens in the classroom and its function in a blended course. A clear and coherent definition of blended must be provided to all involved in blended initiatives. Having consensus about what is meant provides parameters for both the instructor and the learner. Just as students know what internships, laboratories, and practicums involve, so should they recognize what blended means to be best prepared to be successful in both meeting modes.

MEETINGS FOR THE LEARNER

Meeting in the classroom has been a hallmark of the blended delivery mode; regardless of the definition or function, face-to-face interactions are core to the delivery model. However there are limited and mixed reports of what actually occurs in the classroom so the findings in this area are mostly general in nature. More information about what happens in the different modes is described in how courses are chunked, a separate theme.

Many advocate *no* content delivery (such as lecture) should occur in class meetings (Bergtrom, 2011) and while this is suggested by blended effective practices (McGee & Reis, 2012), some reported value for classroom-delivered content. When lectures did occur in the classroom they were offered in response to confusion or misunderstanding (Amaral & Shank, 2010), as a strategy for presenting a case (Hwang & Arbaugh, 2009), or as an introduction to content recorded and then uploaded for online access (Aitken, 2011; Behnke, 2012). Instructor scaffolding was offered as a tactic for presenting new content in the classroom using strategies such as demonstrations (Banerjee, 2011; Behnke, 2012) and guided listening (Hartwell & Barkley, 2010).

More frequently classroom activities were reported to support the learner. These tactics allowed the instructor to answer questions and clarify understanding (Choi, Lee, & Kang, 2009; Gau, 2012; Lopez-Perez, Perez-Lopez, & Rodriguez-Ariza; Ruey, 2010; Precel, Eshet-Alkalai, & Alberton, 2009; Skibba, 2006; Stricker, Weibel, & Wissmath, 2011). Others reported more generic strategies to clarify understanding such as office hours (Banerjee, 2011) and just-in-need discussions (Amaral & Shank, 2010; Behnke, 2012; Carvalho, Lustigova, & Lustig, 2009; O'Byrne, 2011). Classroom sessions also required students to direct clarification through peer-led groups (Amaral & Shank, 2010), peer instruction and questioning (Amaral & Shank, 2010; Behnke, 2012; Hartwell & Barkley, 2010; Laumakis, 2010), and collaborative work on increasingly difficult problems (Liu, et al., 2010).

For a few, classroom meetings were offered as an opportunity for re-connecting with classmates (Geer, 2009; Nguyen, 2011) because a blended environment may lack social presence (Jusoff & Khodabandelous, 2009; Sitter, Carter, Mahan, Massello, & Carter, 2009; Sorden, 2011). Social presence contributes to learning in online environments (Sung & Mayer, 2012) in knowledge sharing (Cross, 2006) and knowledge construction. Other than how content is delivered in lectures, demonstrations or structured listening, blended classroom pedagogy is vague and ill articulated. The focus in the classroom appears to be on management. However, without detailed reports of classroom activities it is not possible to draw conclusions, only pose suppositions. If classroom time is primarily spent clarifying content, directions, or course organization, the connections between the online and classroom environments will not be clear. If content is presented online but classroom time is spent reviewing or clarifying content, it may be the online component is not sufficient to support knowledge acquisition. Finally, what occurs in the class may indicate learner preparedness. Students who understand the dynamics of a blended course can actively participate without extensive instructor prompting or guidance. Those unprepared students may struggle with one or more elements of the course: the course design, independent work, or self-regulation to be prepared for both meeting modes (Holder, 2007; Park & Choi, 2009; Street, 2010; Tyler-Smith, 2006). Xu and Jaggers (2013) found that specific populations struggle to succeed in an online environment: those with lower grade point averages, Black students, younger students, and males in general. The online component may be the most challenging for blended students and from all reports it is a priority for blended course design.

ONLINE PRIORITY

Almost exclusively, reports of blended pedagogy focus on online activities and interactions. Four applications for online activities were prevalent: processing content, discussing, working in groups or collaborating, and completing assessments.

Specific strategies supported student processing content online: reading discussions, presentations (e.g. narrated Power Point™), assignments, and/or quizzes (Amarel & Shank, 2010; Bay & Smith; Banerjee, 2011; Behnke, 2012; Bergson, 2011; Carvalho & Lustigova & Lustig, 2009; Condi & Kay, 2007; Dukes, Moorland, & Scott, 2009; Ernst, 2008; Fulkerth, 2009; Gau, 2012' Geer, 2009; Glazer, 2012; Laumakis, 2010; Lee & Dashew, 2011; Lopez-Perez, Perez-Lopez, & Rodriguez-Ariza; Olapiriyaku & Sher, 2006; Muianga, 2005; Precel, Eshet-Alkalai, Alberton, 2009; Ruey, 2010; Sitter, et al., 2009; Skibba, 2006; Stricker, Weibel, & Wissmath, 2011; Nguyen, 2011; O'Byrne, 2011). Quizzes tended to be offered *for learning* to reinforce reading and provide the learner feedback about their understanding rather than as an assessment *of learning*.

Discussions were the most commonly reported online activity (Bai & Smith, 2010; Bluic, Ellis, Goodyear & Piggott, 2011; Lynch, 2010; Nguyen, 2011; Precel, Eshet-Alkalai, Alberton, 2009; Skibba, 2006; Vaughn & Garrison, 2005). Discussions primarily served as a strategy to reinforce reading assignments, however a few used discussions for teamwork, content clarification, and communication (Gau, 2012; Glazer, 2012; Loureiro-Koechli & Allen, 2010). Discussions were also used to provoke or support deeper understanding through questioning and problem solving (Liu, et al., 2010; Lovell & Vignare, 2009; Sitter, et al., 2009; Skibba, 2006).

Online group and collaborative projects were also referenced as a way for students to connect and produce products over time and outside the classroom (Armellini & Alyegbayo, 2010; Doering, Miller, & Vletsianos, 2008; Hartwell & Barkley, 2010; Liu, Don, Chung, Lin, Chen, & Liu, 2010; Lynch, 2010; Ruey, 2010) extending the face-to-face meetings to the online environment.

While effective practices recommend that assessments occur online (McGee & Reis, 2012), there was little reference to assessment location, however effective practices suggest low stakes assessments supported learning (Behnke, 2012; Bergtrom, 2011; Condie & Kay, 2007; Gau, 2012; Sitter, et al, 2009). For example, Behnke (2012) used assessment primarily to reinforce content; assessments were open book and open friend as students were encouraged to collaborate. As a strategy to prevent cheating, tests were typically set up to randomly order questions, so each student, even if collaborating, would have different answer choices. Test items often referenced source of answer (notes, presentations, readings, etc.). Gua (2012) described an assessment blueprint identifying what course content was assessed formatively and summatively as an indication to students of both function and importance of assessment.

Online activities and requirements focus on supporting the learner to process content through reading, presentations, and interaction between students. Such an approach, for most instructors, requires a course re-design from classroom-based presentation of content. Possibly, the online component is the most challenging to design and implement, and perhaps is the most daunting for those instructors for whom blended learning is a new experience. Processing content and interacting online requires students capable of working independently, have supports available to them when they need them, and technology systems to support the delivery of content and interaction between peers. However, if putting content online is limited to posting streaming lectures and setting up student-led discussions and projects, the blend is not complete. Assumptions that technology will take care of students when they are online suggest a hybrid approach rather than a blended one. In the hybrid approach connectivity with course members and course processes are turned on and off depending on the delivery mode. In a blended approach, students are experiencing the affordance of the technologies and meeting modes.

TECHNOLOGY WITH A PURPOSE

There were distinct references to the *function* of the technology to support course delivery and learning in the *online* environment with little to no reference about technology use in the classroom. Technology references indicate that it is axiomatic to the online experience in ways that were pedagogically articulated.

Technology tools, both within a course management system and through the use of external tools (e.g., phone, texting, Skype™, etc.), were a primary medium for communicating between students (Chen, 2007; Dawson, 2010; Geer, 2009; Glazer, 2012; Heckman & Annabi, 2006; Inoue, 2010; Lee & Dashew, 2011; Liu, Don, Chung, Lin, Chen, & Liu, 2010; Loureiro-Koechlin & Allen, 2010; O'Byrne, 2011; Precel, Eshet-Alkalai, Alberton, 2009; Ruey, 2010). The value of communication through technology suggests work is going on between class sessions and students accept this mode of communication, not relying on face-to-face meetings as the primary form of interaction with peers or instructor. In this way technology most likely serves as a bridge between environments.

Technology was also used to disseminate content produced by the instructor or external sources (Anderson & May, 2010; Carvalho & Lustigova & Lustig, 2009; Condie & Kay, 2007; Doering, Miller, & Vletsianos, 2008; Dukes, Koorland & Scott, 2009; Ernst, 2008; Fulkerth, 2009; Hartwell & Barkley, 2010; Laumakis, 2010: Liu, et al., 2010; Olapiriyaku & Sher, 2006). Some courses integrated technology to include student produced content, such as podcasts, wikis, and blogs (Fulkerth, 2009; Lin & Kelsey, 2010; Lopez-Perez, Perez-Lopez, & Rodriguez-Ariza, 2011; O'Bryne, 2011; Precel, Eshet-Alkalai, & Alberton, 2009; Sitter, et al., 2009).

Collaborative/group/team work was also supported in online environments (Banerjee, 2010; Doering, Miller, & Vletsianos, 2008; Dukes, Koorland, & Scott, 2009; Engstrom, 2010; Geer, 2009; Glazer, 2012; Lin & Kelsey, 2010; Liu, et al., 2010; O'Byrne, 2011; Precel, Eshet-Alkalai, & Alberton, 2009; Ruey, 2010; Skibba, 2006; Stricker, Weibel & Wissmath, 2011). In some instances students worked online to complete work, while in other situations students used technology to organize their ideas, create presentations, or collect and share references.

Finally, technology was used to support student *practice* of their learning in a variety of ways. Individual students may practice through simulations, quizzes, tutorials or games (Bai & Smith, 2010; Chen, 2007; Nguyen, 2011; Stricker, Weibel, & Wissmath, 2011). Practice may also take the form of collaborative and open exchanges as described in Ng'ambi & Brown's (2009) *Dynamic FAQ* tool. This tool is an anonymous web-based program and mobile SMS phone system through which students can consult with each other and the lecturer as they have questions or needs. Students can also search the system for answers, schedule a concept lecture or an assessed tutorial. Such a strategy provides flexibility and support as the student needs it rather than waiting for a face-to-face or online meeting.

Just having technology present does not ensure it can or will support learning. Our increasing understanding of how technology can be aligned with learning theory informs us about the function of tools, and how best to integrate them in the classroom, online, or on the go as learners have access anywhere and anytime (Olofsson & Lindberg, 2012). For the blended learner technology supports connectivity to others, access to resources, and participative activities not unlike a 100% online course. In blended courses technology is used as a support for accomplishing a specific outcome rather than engagement or social presence alone. Technology is aligned with a specific pedagogical function and thus, perhaps, is utilized more effectively and meaningfully than in courses where technology use is ancillary to course outcomes or processes. Such relevant and focused interactions are more likely to keep students engaged.

FOCUSED E-INTERACTIONS

Reports indicate blended course interactions occurring online are specific and relate to course objectives. These findings overlap those of the previous theme, however they are distinct because the intentional use of technology is described in relationship to the overall pedagogical design through specific strategies. Discussions are uniformly the most used strategy for online interactions, followed by purposeful peer-to-peer interaction.

Discussions are the most referenced form of online interaction in blended courses in effective practice guides (McGee & Reis, 2012). In this study, discussions were used for clear purposes: to build deeper comprehension of course content (Bluic, Ellis, Goodyear, & Piggott, 2011; Chen, 2007; Gau, 2012; Geer, 2009; Skibba, 2006), encourage open and critical discussion (Chen, 2007; Heckman & Annabi, 2006); and to bridge class meetings with a relevant activity (Carvalho & Lustigova, & Lustig, 2009; Condie & Kay, 2007; Engstrom, 2010; Hwang & Arbaugh, 2009; Inoue, 2010; Lidstone & Shield, 2010; Ruey, 2010; Skibba, 2006; Stricker, Weibel, & Wissmath, 2011). Discussion focus was on learner-to-learner interactions with little reference to the instructor's participation indicating learners are active and responsible for making sense of their own knowledge acquisition.

Online discussion was also used to allow students to scaffold and peer tutor each other. Group or team work was often situated in discussions, either as a strategy to support group work, or as a way to help students learn from each other (Armellini & Aly-egbayo; Behnke, 2012; Dreher, Reiners, Dreher, & Dreher, 2009; Behnke, 2012; Dukes, Koorland, & Scott, 2009; Gau, 2012; Lidstone & Shield, 2010; Liu, Don, Chung, Lin, Chen, & Liu, 2010; Muianga, 2005; Nguyen, 2011; Skibba, 2006; Stricker, Weibel & Wissmath, 2011). Such approaches enabled learner autonomy (in decision-making through contributions) and self-awareness (as their ideas are put in context with the ideas of their peers) while diminishing a feeling of aloneness that may occur when students are physically separated.

Peer-to-peer interaction was another type of interaction providing feedback to learners and helping to clarify understanding through strategies such as critiques, dyads, and study teams or groups (Carvalho & Lustigova & Lustig, 2009; Chen, 2007; Dukes, Koorland, & Scott, 2009; Engstrom, 2010; Geer, 2009; Lee & Dashew, 2011; Lin & Kelsey, 2010; Loureiro-Koechlin & Allen, 2010; Ng'ambi & Brown, 2009; O'Byrne, 2011; Ruey, 2010; Vat, 2010). Peer-to-peer interaction facilitated social presence and active learning through repeated and ongoing exchanges reinforced through classroom meetings.

The function of interaction in online learning environments has been well documented. Moore (1993) proposed that interaction impacts transactional distance between learners and instructor thereby reducing the effect of distance created by not meeting face-to-face. More recently, evidence indicates interaction provides a variety of benefits to the learner:

1. Some research indicates students learn better when they 'do' as opposed to 'receive' content. In this sense the learner is interacting with the *content* or acquiring knowledge through a *process*;
2. Interaction can decrease the sense of isolation students may experience when working out of the classroom;
3. Interaction *can* facilitate *divergent* thinking. However, if not carefully framed interaction may not support *convergent* thinking. In other words, students may get lost in too much information not consolidated or synthesized;
4. There is evidence social presence supports learning and interaction increases social presence (Swan, 2004).

In a blended course it may be crucial to maintain social presence through interaction, not just to personalize the instructor but also to connect learners across meeting modes, In this study, online interactions were purposeful and focused, but they did rely heavily on text-based interactions – there was little reference to non-text based tools, such as video-conferencing or concept mapping, for the purpose of learning. There is some evidence that seeing the person to whom you are communicating lessons transactional distance and reinforces community and presence (Kim, Kwang, & Cho, 2011). For example, the use of avatars has increased levels of trust and intimacy in online collaborations (Bente, Ruggenberg, Kramer, & Eschenburg, 2008). Students most likely use highly interactive tools (such as FaceTime™, Facebook, or Skype™) without the instructor's knowledge, thereby establishing a community relying on a much richer environment afforded by asynchronous text. These kinds of environments are much more likely to support active learning.

ACTIVE LEARNING

The reviewed literature indicated a clear use of active learning strategies either informing the overall course design or directing short-term activities. Active learning is situated in the idea that students are more likely to learn when they are aware of their *existing knowledge*, and when they are conscious of what they do *not* know (Bransford, Brown & Cocking, 2000). The use of metacognitive strategies allows students to reflect upon their developing knowledge and to monitor their own learning. Blended learning is well situated to support active learning because students are engaged both in and outside of the classroom requiring some degree of self-sufficiency and decision-making.

Most of the strategies reported were ones familiar in face-to-face classes however a blended design provides more options for active learning because students work independently or with others to direct the learning process, or complete projects outside of the classroom (Lynch, 2010). Group work was typically described as collaborative learning (Banerjee, 2011; Chen, 2007; Hartwell & Barkley, 2010; Liu & Tortellon, 2011; Liu, et al., 2010; O'Byrne, 2011; Stricker, Weibel & Wissmath, 2011). Collaborative learning requires individual team members to work independently to complete one piece of a larger project, which, when combined create a complete project. There were two strategies employed for collaborative work. First, students worked completely online to develop their component of a project, and then presented it in the classroom setting. Second, students organized in the classroom setting and finalized their part in the online environment. In either case, students worked independently of the instructor's close monitoring and managed their own schedule and activities.

Common to the campus classroom, debates, cases, and projects differed slightly in blended courses. Debates provided an opportunity for students to prepare online - individually or as a team - and then conduct the debate in a face-to-face meeting (Carvalho & Lustigova & Lustig, 2009; Gerbic, 2009; Yukawa, 2010). For some, face-to-face meetings were also used for planning, consultation with the instructor, or rehearsal. Cases were used in the classroom and online to allow students to discuss and interact as they put forth their solutions (Choi, Lee, & Kang, 2009; Glazer, 2012; Liu & Tortellon, 2011; Precel, Eshet-Alkalai, Alberton, 2009; Skibba, 2006). Projects were often used as a longer assignment in which students worked outside of class, typically coming to class for instructor support, discussions, or work sessions (Behnke, 2012; Hartwell & Barkley, 2010; Dreher, Reiners, Dreher, & Dreher, 2009; Olapiriyaku & Sher, 2006; Ruey, 2010).

Inquiry (Banerjee, 2011; Chen, 2007; Geer, 2009; Ruey, 2010; Sitter, Carter, Mahan, Massello, & Carter, 2009; Vat, 2010) and discovery learning (Inoue, 2010; Liu, Don, Chung, Lin, Chen, & Liu, 2010) were strategies for student investigations. While inquiry and discovery learning have common roots in science education they differ pedagogically. Discovery learning was originally conceptualized by Bruner (1961) as an approach to teaching in which the learner learns by doing, specifically through problem solving. For example, the blended CELL (Contributing, Exchanging, and Linking for Learning) project (Liu, et al., 2010) utilized software that recorded individual and group web-based inquiries via mobile (out of class) and shared display (in class) supporting discovery learning (Inoue, 2010). Adventure–based learning builds on discovery learning through active participation of the learner in authentic activities as they assume real world roles and access authentic tools and materials (Doering, Miller, & Veletsianos, 2008). Inquiry learning is more focused on students answering questions, either provided to them by instructors or posed by peers. In a blended context, students might be given questions to answer online, then return to class to synthesize or present findings or clear up confusing aspects of what they have learned. A combination of inquiry and discovery is evident in the Acquisition Model + Participation Model. In this approach students were given more responsibility for their learning with a high level of participation, communication, and interaction with peers (particularly in the online mode) and for monitoring their learning (Bergtrom, 2011; Dreher, Reiners, Dreher, & Dreher, 2009; Hwang & Arbaugh, 2009; Inoue, 2010; Lidstone & Shield, 2010; Muianga, 2005; O'Byrne, 2011).

Active learning engages and places responsibility on the learner within a well-defined pedagogical framework. The shift toward student ownership and self-direction indicate blended learning is learner-centered and focused on deeper learning (Carmean & Haefner, 2002). The emphasis on active learning suggests students are self-regulated, disciplined, and motivated to work independently and with limited direction from the instructor. Designing a course for active learning requires careful preparation, directions, and supports for students who may not have the experience to participate in ways expected of them. In blended courses, the use of active learning may also relate to how class meetings are structured and how frequently they occur.

DISTRIBUTION OF TIME

Many definitions of blended course delivery are in part defined by the amount of time students spend in the classroom and online, however, as indicated in this study, there is a wide range of reported distribution of classroom and online activities. Brown (2001) found blended courses ranged from between 90–10% and 10–90% distributions of face-to-face and online sessions. Allen, Seaman and Garrett (2007) suggest a range from 30% to 79% in either online or face-to-face modes. Given such variations, it is not clear if time distribution is critical to a blended course.

The most frequently reported distribution was 50% online and 50% in the classroom, or meeting in person once a week (Carvalho & Lustigova & Lustig, 2009; Choi, Lee, & Kang, 2009; Ernst, 2008; Fulkerth, 2009; Gau, 2012; Hwang & Arbaugh, 2009; Hwang & Arbaugh, 2009; Laumakis, 2010; Lopez-Perez, Perez-Lopez, & Rodriguez-Ariza, 2011; Sitter, et al., 2009; Skibba, 2006). A slight variation was reported as 35% classroom, 65% online (Inoue, 2010).

A few designs utilized flexible attendance in which students had a choice about whether to attend the face-to-face meetings. Such an arrangement is articulated in the Hyflex model (Beatty, 2010) where students make choices about where and how to interact and participate (Dreher, Reiners, Dreher, & Dreher, 2009). Typically those who used flexible attendance had students who were participating outside the local area and would never be able to attend a face-to-face meeting (Lidstone & Shield, 2010; Muianga, 2005; Precel, Eshet-Alkalai, Alberton, 2009). Even more flexible designs allowed students to proceed through online modules in any order at their own pace as they completed content. For example, Harwell and Barkley (2012) conferred points to students as they proceeded through course objectives. If students could adequately complete assessments they were allowed to skip modules. In this flexible model students chose to attend or not to attend face-to-face sessions or to work in teams. Student choice also was indicated in community of practice approaches allowing students to make decisions about amount and purpose of interaction, attendance requirements, and the process of negotiating understanding (Lidstone & Shield, 2010; Liu & Tortellon, 2011).

Other time distributions were related to the needs of the course rather than a structured schedule. Gua (2012) offered 15 scheduled meetings per semester in six lecture groups students elected to attend. Students were exposed to course content at different times but in smaller groups creating greater intimacy and convenience. Skibba (2006) utilized a varied approach with some concentrated sessions shifting to online or non-regular meetings based on class needs and consensus. The least reported classroom meeting strategies were those where classes only met three times of the semester: at the beginning, middle, and end (Ruey, 2010; Nguyen, 2011).

Reasons for frequency or schedule of meetings were not clearly articulated. It may be classroom availability, scheduling of meeting spaces, or policies regarding faculty contact with students impacted when and how frequently meetings were scheduled. Not understanding schedules may distort pedagogical designs. If institutions require instructors meet once a week then pedagogical requirements would work around meeting requirements and possibly contrive the reasoning for a class meeting. It is the author's belief that course content, student need and pedagogy should inform when and how students meet.

PEDAGOGICAL CHUNKING

A distinctive feature of blended courses is how they are organized into segments providing a form of pedagogical structure. The concept of chunking originated with George Miller's (1956) principle of the human ability to process 7+2 pieces of new information. Miller's work led to cognitive load research particularly relevant to designing instruction in general but specifically to blended course design because blended courses are segmented into well-articulated parts eventually related to each other. Chunking is evident in the concept of layering or how course components relate to each other.

Layering is discussed in different ways, however generally layers address what Derntl and Motschnig-Pitrik (2004) describe as the structural (where learning occurs and how it is connected) and dynamical dimensions (the shift on the focus on technology to learning which occurs over time) of blended learning. Derntl and Motschnig-Pitrik's Blended Learning Systems Structure (BLESS) provides a technical model to inform the layering process:

Layer 1: This layer focuses on what the learner 'sees' as they approach a *blended course* in their person-centered way of participating in educational activities. In this layer the prior knowledge and expectations are key in considering how the course is presented to the learner;

Layer 2: Derntl and Motschnig-Pitrik argue for providing clearly articulated *course scenarios* which conceptually model and visualize course content as a step toward helping students recognize course patterns, ultimately creating a course schema;

Layer 3: Layer three requires intentional and direct communication of *blended learning patterns* guided by humanistic education principles. This layer supports transparency, self-direction and peer learning through discussions, sharing content, face-to-face brainstorming, etc. These are learning processes utilized in blended courses;

Layer 4: *Web templates* are the focus of this layer as they organize content and interaction operating through the CMS and allowing course patterns to be viewed from three perspectives: participant, administrative, report. This layer does not necessarily or directly relate to pedagogy, although depending on the course content it could. For example, a course designed around research might use a process template for proposals, data collection, data analysis, drafts, and final reports. Essentially this layer builds data collection strategies into the course through which progress can be monitored and tracked;

Layer 5: The *learning platform* is layer 5. Each CMS has certain functions, elements and operational requirements determining how things work (such as discussion participation) and how they can be accessed (through the templates in Layer 4).

In Derntl and Motschnig-Pitrik's model, pedagogy is suggested but not articulated. Pedagogical layering is more straightforward and provides a broad framework for understanding the unique character of blended courses in which what the learner does must be considered in both *where they are* and *what is required* in order for learning to occur. Glazer (2010) illustrates layering in the following way:

Part 1: *Introduce case* (e.g., five roles and five teams not assigned a role) and basic concepts (covered in class);

Part 2: *Elaborate on core content.* The instructor provides an opportunity for investigation (e.g., online in private group discussions);

Part 3: *Mediate conflicts of investigation*. The instructor provides ways for students to consider areas of disagreement (e.g., role play in class but prepare online).

At the highest level, the notion of layering illustrates a general approach to chunking in which content review and rehearsal precedes face-to-face interaction (Aycock, 2012; Ernst, 2008; Gau, 2012; Glazer, 2012; Skibba, 2006). Such content review might include virtual labs, streaming lecture/podcasts, reading, and formative assessments such as quizzes over content covered. Such a strategy in itself places the responsibility on the learner to be prepared for class meetings. A new schema of how learning works is created for the learner who, in other courses, might expect the instructor covers all content in the classroom.

Even though layering occurs in different ways by different instructors, pedagogical templates can provide the basic components for a design. All of the following templates articulate location and sequence of learner activity, reflecting the active learning nature of the blended delivery model, and emphasizing learner-centeredness. Some layering approaches are general, allowing much interpretation and variability. Fulkerth (2009) focuses on the blend in thinking about how to transition between the classroom and online activities in bridging activities. He illustrates what bridging activities should accomplish in the following list:

1. **Revisit Past Learning:** The instructor reviews and reinforces what students have already learned;
2. **Integrate Current Learning Through Multiple Processes:** e.g., analysis, interpretation, translation for classmates, creating transparency;
3. **Foreshadow What Comes Next:** The instructor reviews upcoming content, thoughtful reading and summary, aimed at student and self-learning (p. 52).

Many layering techniques are specific to the discipline and clearly structured to support pattern recognition of course structure. For example, Glazer's (2012) sees three components in her courses reflecting the applied and practical nature of education:

Part 1: Introduction of a relevant case (for example, five roles replicated in each of five teams) and basic concepts are presented in class;

Part 2: Elaboration on core content with an opportunity for further investigation occurring online in private team discussions;

Part 3: In class, the instructor facilitates mediation of conflicts possible among and across team investigations. Role-play is also conducted in class, but preparation occurs online.

Ernst (2008) presents a coherent and patterned structure of his blended technology course in which students advance lockstep through a repeated sequence of events, activities, assignments and assessments:

1. Students viewed weekly online video lectures (narrated PowerPoint™);
2. After viewing video, students posed questions about the content to a discussion area;
3. After viewing the online lecture students were prompted to complete a hybrid online survey to monitor the course itself;
4. The instructor conducted weekly laboratories in part to clarify any misunderstanding and provide hands-on experience.

Other formulas focus on discrete components of the learning process – what the learner does to take in content, how they practice, and how they conclude an instructional sequence. All of these include content review with some form of active processing: watch case, write reports, access primary data (Choi, Lee, & Kang, 2009); view online lecture once a week, attend teacher directed lab once a week (Ernst, 2008); view weekly online video lecture and submit questions online through forum then meet in a class lab to clarify questions (Lopez-Perez, Perez-Lopez, & Rodriguez-Ariza, 2011); read online with weekly online and classroom discussions (Nguyen, 2011); complete teamwork online, post response to topic every three weeks and present findings in class (Geer, 2009); and, examine related websites in class, complete online learning activity, and debrief and review in class (e.g. prepare a defense, critique, etc.) (Aycock, 2012).

The amount of detail, or lack of detail, regarding pedagogical chunking raises questions about the true meaning of blended course design. In this study, online activities appear to be rich and used to support learning in a meaningful way. However, it is not clear that more value is placed on one setting or the other. In *pedagogical* chunking a relationship between the online component and the face-to-face component is evident. However, in general, more emphasis is placed on what happens online. Focusing on the online component suggests what happens in the classroom is less of a priority and is not pivotal to the learning experience. For example, Hwang and Arbaugh (2009) make it clear what happens in each location:

1. **Face-to-Face Class:** The instructor introduces the topic for the week with a short lecture and then poses questions or a short case for students to apply the taught concepts;
2. **Online:** The class is carried online in a discussion where the instructor poses questions to which students respond and work with each other in clarifying each other's discussion posts.

While illustrating pedagogical chunking, Hwang and Arbaugh's description could be interpreted as web facilitated (Allen, Seaman, & Garrett, 2007) if the authors had not claimed a blended format. Pedagogical chunking makes clearer what students are doing in both modes and how the modes are connected to support student learning.

Overall, the chunking of activities between and across modes provides unity to the course and, as often noted, releases the instructor from lecturing (Geer, 2009; Aycock, 2012). Cognitive load theory indicates learners have limited cognitive capacity during learning (Sweller, 1994). Chunking content in ways relating to existing schema and providing support for adding to or creating new schema can support learning (Sweller, Marienboer, & Paas, 1998). Sweller (1994) argues *extraneous* cognitive load distracts the learner and diminishes learning while *germane* cognitive load support schema construction. Poorly designed instruction triggers extraneous cognitive load. Thus strategies that "chunk" or layer the course in a meaningful, coherent, and consistent way are more likely to support learning while creating a 'schema' for the blended course framework. While blended courses are not layered in the same way, it is possible providing clarity, repetition, or relevance in course organization is key to making the learner's cognitive load manageable. Most important is the blend itself – pedagogical chunking has the potential to make the connections between activities meaningful and relevant in equally important ways. The range of strategies summarized here is not without exceptions, however, which may indicate potential hidden advantages or disadvantageous omissions.

OUTLIERS AND OMISSIONS

The previously reported themes suggest variations in blended course design, but there are some areas that, while not common, stand out as not following the mainstream. It also should be noted what is omitted or overlooked in reports of blended course pedagogy may be just as important as that which is described.

Assessment was superficially addressed, or not at all, in the studies analyzed. An exception was Behnke (2012) who clearly stated where and what kind of assessments were used; high stakes tests (midterm and final) occurred in class. McGee and Reis (2012) found that effective practices also downplay the placement of assessment and do not clarify how blended assessments differ from classroom or online course assessments. With an emphasis on active learning it maybe that blended courses offer more performance assessments evaluated in benchmarks rather than high stakes objective tests. Or it may be that assessments are directly translated from the face-to-face course into the blended course with little or no transformation and thus not included in reports about blended pedagogy. Effective practice guides emphasize alignment (Snart, 2010) between objectives, activities, assignments and assessments yet the literature examined did not reveal an alignment process.

While there is evidence to suggest that utilizing a blended course design shifts the nature of the course as well as the role of the instructor, this was not the case in all reports. There was one report of classroom *content* presentations by instructor (Olapiriyaku & Sher, 2006). Skibba (2006) expressed that the online component was an extension of what occurs in the face-to-face meetings, suggesting that what happens in the classroom is what was most important and perhaps better reflecting a supplemental design in which online activities supplement the face-to-face meetings.

Because most literature reports focused on online interactions, yet reported meetings in regular classrooms, it is not clear how the blend between the classroom and online environments works in general. Reports describe what happens in both modes but little is offered in expressing the blend between them. It may be what is overlooked in reports of blended pedagogy is the iteration over time as the traditional course is phased into a truly blended one. Bergtrom (2011) illustrates this process (Figure 1) as each offering of the course increasingly shifts content online.

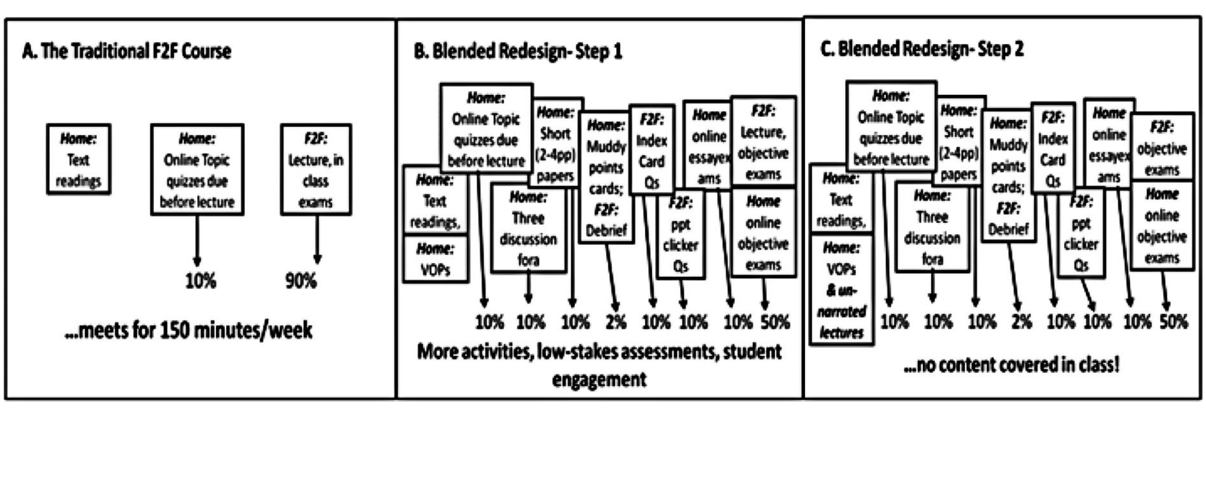
Published literature may report the first, third, fifth or other iteration of a blended course thereby presenting a different stage in a course's evolution towards a full blend. What may not be presented in blended literature is the evolution of a blended course, verifying Bonk and Graham's (2005) concept of the transformative blend that radically changes an instructor's pedagogy.

CONCLUSION

This study was conducted in order to identify characteristics of successful blended courses. Findings indicate that blended courses rely on technology for purposeful interactions, utilize a coherent course organization (indicated by pedagogical chunking), and are learner-centered as they actively engage the learner. The findings reflect principles of sound instructional design and for the most part mirror blended effective practices. Questions remain about what is not reported in the literature that may impact on the potential success of blended courses.

Interactions within a blended or hybrid course are typically technology-mediated or facilitated, with classroom sessions optionally scheduled to provide intensive work sessions. The emphasis on online interactions implies students know what to expect or are prepared

Figure 1. Shifting from F2F to blended course redesign (Bergtrom, 2011)



to interact in ways possibly not experienced in a traditional web facilitated or face-to-face course. Readiness is surely core to student success in technology rich courses and successful strategies for understanding student skills will be a useful contribution to designing successful courses.

Course organization appears to be somewhat formulaic if not tightly structured around pre-ordained schedules. Findings from this study indicate activity and/or location is the primary driver to organization. However, effective practices indicate objectives should drive how the course is blended (McGee & Reis, 2012), see Table 1. The commonly reported 50% in class and 50% online meeting distribution typically enacted as meeting once a week makes a true blend somewhat questionable and more akin to a web facilitated course in which online activities supplement classroom activities. Layering strategies make the blend more coherent by illustrating what students do when and where as relates to an overall course experience. More examples and rationales for how and why blended courses work across locations will reveal principles to guide the design of a course that is truly blended.

This study is limited because in order to identify sufficient pedagogical descriptions the author put few limits on the published literature from multiple disciplines using varied research methods (if at all) with different research questions. While this high level analysis is informative, it does not reveal deeper patterns possibly impacting pedagogical designs. For example, any of the following may impact pedagogical designs: institutional support of learner preparedness, instructor years of experience in course design or teaching, utilization of university supports, Carnegie classification (reflecting mission and priorities), and institutional policies (with requirements for interaction, assessment, class meetings, or class size). Additionally, because most reports represented disciplinary perspectives there may exist patterns within a subject area. It is not clear how instructors made decisions based on their *content* knowledge, knowledge of *pedagogy* or e*xperience* with technology (Mishra & Koehler, 2008).

Table 1. Disconnect between recommended practices and reported pedagogy

Effective Practices Recommendations (McGee & Reis, 2012)	Pedagogical Patterns
Focus on objectives to determine the blend	Focus on activity and location to determine the blend
Integration between F2F and online	Report online, F2F is a valued requirement
Varied interactivity	Pedagogical template vs. routine activity
Varied assessment	Emphasis on formative assessment

The use of technology in a face-to-face, blended, or 100% online requires different ways of conceptualizing activities and assignments within the constraints of the delivery mode, hopefully building upon the affordances of technology to best support content learning. But more is required of the instructor who designs and implements a blended course. For those faculty members who have once taught in face-to-face classrooms, shifting to a blended approach surely initiates pedagogical transformation in part through the reliance upon technology.

As reports of blended/hybrid pedagogy continued to be published articulated patterns must be captured in order to best understand how and why blended course design can be successful and allow a cohesive pedagogical model to be developed. It would be most useful if researchers and reporters answered the following questions:

1. What about the course content made it a good fit for blended delivery?
2. How were the classroom and online activities connected?
3. What determined what occurred in the classroom and what occurred online?

4. To what extent were learners prepared to participate in a blended course?
5. In what ways did the course and instructor behaviors change in the shift from classroom to blended?
6. What, if any, iterations occur contribute to a well-crafted blended course?

Chapter 29
A Teaching Model for the College Algebra Flipped Classroom

Lori Ogden
West Virginia University, USA

Laura J. Pyzdrowski

Neal Shambaugh
West Virginia University, USA

ABSTRACT

A flipped classroom teaching approach has been used in the teaching of college algebra within a broader initiative for mathematics learning. The flipped classroom approach documented in this chapter utilizes multiple teaching strategies to enhance student learning. From the pilot teaching of two semesters of college algebra, a teaching model was developed using the Joyce, Weil, and Calhoun (2009) framework. The purpose of this study and chapter is to describe the design and development of the flipped classroom teaching model in terms of the design decisions, model implementation, and model evaluation over the two semesters. Student survey responses and interview results suggest that this teaching model improved student perceptions of learning college algebra. Findings reported in this study document the use of the model, while future iterations of the design and development cycle (Richey & Klein, 2007) are necessary to understand the impact of the flipped classroom model on student learning.

INTRODUCTION

According to Haver (2007), the percentage of students withdrawing or earning grades of a "D" or "F" in college algebra courses nationally is more than 45%. One explanation from Harver is that most college algebra classes focus exclusively on algebraic manipulation skills and spend little time if any on applying these skills outside the classroom. Researchers have identified factors that may contribute to high failure rates in entry-level undergraduate mathematics courses, including a

DOI: 10.4018/978-1-4666-8246-7.ch029

student's background knowledge, self-efficacy, perception of the usefulness of mathematics, and motivation (Cardetti & McKenna, 2011; Hall & Ponton, 2005; Thomas & Higbee, 1999). College algebra is often referred to as a "gateway course," one that students must pass before they are allowed to enroll in other courses. Undoubtedly, passing or failing college algebra influences a student's career choices and a student's career trajectory. Changes must be made in the delivery of college algebra in an effort to enhance a student's self-efficacy, motivation, and perception of mathematics, ultimately leading to a rise in student performance.

Bandura (1997) defined self-efficacy as the personal belief in one's ability to be successful at specific tasks or to achieve a specific goal and that an individual relates their self-efficacy to past experiences. For example, in an academic context the nature of a student's experience in a high school mathematics class, positive or negative, might impact how that student feels about his ability to succeed in a mathematics course in college. Hall and Ponton (2005) found that when a student related academic achievement to their personal capability and exerted effort, their mathematics self-efficacy increased.

The National Council of Teachers of Mathematics (NCTM, 2000) associated effective teachers of mathematics with a strong commitment to their students as learners of mathematics and their capability of using a variety of pedagogical and assessment strategies. NCTM (2000) further acknowledged that "students will be served well by school mathematics programs that enhance their natural desire to understand" (p. 21). Ideally, students enter school with knowledge from their cumulative past experiences, both personally and academically, so teachers must design instruction that elicits a student's need to further his understanding and deepen his existing knowledge (Garrison, 2010). Since students' self-efficacy, past experiences, and needs and desires are different from those of their peers, mathematics educators must use a variety of instructional strategies to engage students, elicit their natural desire to learn, and to reinforce the notion that their learning is possible. Walter and Hart (2009) conducted a teaching experiment where students were invited to work together on tasks that were carefully designed to elicit a mathematical need and found that a conceptually-driven classroom elicits a student's intellectual passion and motivates the student to learn, again reinforcing the idea that teaching strategies can impact students' perceptions of learning.

A pedagogical approach called flipping the classroom could provide instructors of college algebra an opportunity to address the factors that may contribute to high failure rates in entry level undergraduate mathematics courses; specifically, self-efficacy, perception of the usefulness of mathematics, and motivation. The subsequent sections of this chapter will describe the design, implementation, and evaluation of a flipped classroom teaching model used to teach undergraduate students college algebra at a land-grant university in the eastern United States.

BACKGROUND

Teaching Context

Innovative teaching in college algebra has been an ongoing aim at a land-grant university in the eastern United States, and the flipped classroom framework is one step in the continuum of ongoing improvement. One of the goals of the department of mathematics is to incorporate online learning components into entry-level mathematics courses. The department now has an 80-seat and a 120-seat instructional computer laboratory, which enables targeted courses such as college algebra to have dedicated weekly seat-time for all enrolled students. In a given fall semester, there are approximately 1500 on-campus students enrolled in college algebra. The undergraduate mathematics courses share an overarching goal of improving student learning, conceptual understanding, and abilities to apply mathematics to solve problems via the use of technology. In addition to meeting multiple times a week for a lecture, college algebra students make use of online, interactive applet computer laboratories, which focus on conceptual understanding, problem solving, and the application of mathematics, as well as online homework assignments for skill acquisition. Faculty members are also charged with conducting research to support change in instruction, curriculum development, and assessment. This project has led instructors to implement a flipped classroom framework to determine its effects on students' self-efficacy, understanding, and performance in college algebra.

The flipped classroom approach has been used in classrooms on a number of college campuses over the last several years; however, there may be some confusion as to what a flipped classroom approach is and what it is not. For example, Lage, Platt, and Treglia (2000) implemented what they called an inverted classroom approach in an undergraduate economics course. In their model, students were asked to read about an assigned topic before class. Videos were made available outside class for students to view in two different formats, while face-to-face class time was used for "hands on" experiments. They found that students generally preferred the inverted classroom to a traditional lecture. One student said, "I learned more than I ever thought I would in a new, creative, and inspiring way" (Lage et al., 2000, p. 35). Videos were not made mandatory for students, but preparing for the face-to-face class via reading the text was. A flipped classroom approach to teaching is not just the implementation of instructional videos but a pedagogical design that replaces what typically takes place during a face-to-face lecture (passive transfer of knowledge) with engaging activities and assigns the lecture as homework for students to complete autonomously outside of class. However, the mere implementation of instructional videos, albeit effective, does not imply a classroom flip. Videos can be produced for a myriad of reasons including remediation, review, homework solutions, or supplemental lectures (Azedevo, 2012, Green, Pinder-Grover, & Millunchick, 2012, Rose, 2009, Toto & Nguyen, 2009). Green et al. (2012) successfully implemented screencasts into their introductory engineering class, but not in the form of what is traditionally known as a flipped classroom approach. Two types of screencasts were made available to students, optional videos that provided homework solutions and optional videos that provided mini-lectures. Although students who watched the videos found them to be helpful, the researchers did not indicate that videos were used to replace a traditional form of instruction. A flipped classroom approach uses video to bring engaging activities into the classroom without losing the necessary lecture component of the course. The flipped classroom approach can help instructors provide their students with a solid knowledge base through at-home instruction and an opportunity to apply that knowledge in engaging classroom activities.

Pedagogy: Framing the Flipped Classroom Teaching Model

Although the idea behind the flipped classroom is not new, there are few formal and comprehensive studies focused on this pedagogy. Preliminary results from a number of studies have indicated positive results. For example, instructors at one university chose to implement pre-existing video lectures into one of their engineering courses. After watching videos at home, students were expected to apply the knowledge gained from the videos by participating in discussions and activities in class. Preliminary data indicated that students in the flipped classroom outperformed their traditionally taught peers on the midterm exam (Azedevo, 2012). Another variation of the flipped classroom was piloted in a junior level engineering course at another university. Unlike the previous approach, instructors at this university authored their own videos. Although a similar classroom format was followed, student feedback regarding the teaching approach indicated that students felt the video lectures were effective in teaching them the material, but that the classroom activities were disorganized and caused some to students fall off task (Toto & Nguyen, 2009). The student feedback suggested that simply implementing video lectures outside of class is not enough to impact student learning. What replaces the lecture during face-to-face class time is integral to the success of the flipped classroom teaching approach. The flipped classroom can take many different forms and can be modified to meet the specific needs of students.

Flipping the classroom can provide an opportunity for teachers to design a classroom environment that addresses students who may be averse to learning mathematics. Stage and Kinzie (2009) suggested that reform efforts are never a universal fix and cautioned "reform must be tailored to individual classes and be consonant with the instructors' strengths and subject matter and students' needs" (p. 103). In essence, the flipped classroom approach is a teaching approach that uses multiple teaching strategies to enhance student learning, but like any other approach must be carefully studied over time to reach its full potential.

The Flipped Classroom Teaching Model

The use of the flipped classroom teaching strategy would benefit from being situated within a formal teaching model to provide an explicit description of the full range of procedures and conditions needed to successfully implement the model, teaching decisions, and results of using the model. The flipped classroom approach was documented as an integrated teaching model, acknowledging multiple teaching approaches, including in-class cooperative learning, mentored laboratory activities, and online teaching videos (see Figure 1).

The integrative model was documented using the Joyce, Weil, and Calhoun (2009) framework, which includes the following components:

- Syntax or procedures for using the model,
- The social system describing student and teacher roles and relationships,
- Principles of reaction from students and subsequent decisions from teachers,
- The support system necessary to provide the conditions for efficient and effective model implementation, and
- The instructional (direct) and nurturant (indirect) effects of the model.

Syntax

The syntax or procedural flow of this course is based on research conducted on two case studies and includes three phases for each delivery of the course. The phases are:

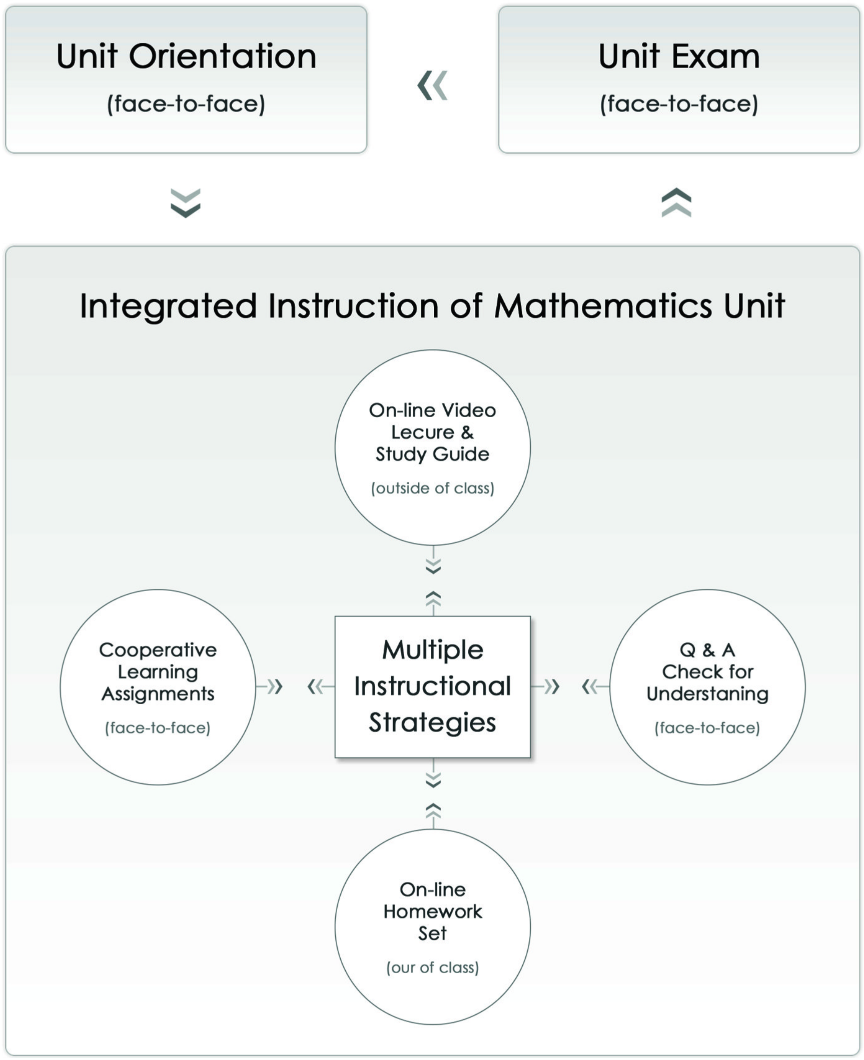
- Orientation to the mathematics unit;
- Instruction of the mathematics unit, which consists of the following:
    - On-line video instruction and study guide completion outside of class,
    - Question and answer session face-to-face,
    - Online homework outside of class,
    - Cooperative learning assignments face-to-face in the classroom or in the computer laboratory; and
- Unit exam assessment face-to-face.

The sequence of phases one through three is illustrated in Figure 2. The following syntax description is based on the instruction of one of five units taught in a college algebra class that meets for 50 minute class sessions, five days a week.

Phase 1: Orientation to Mathematics Unit

Phase one of the teaching model begins with the instructor introducing the algebra unit to be studied over the next cycle of the course and briefly describing each section of material to be covered within the unit. Each student is given a

Figure 1. The flipped classroom teaching model



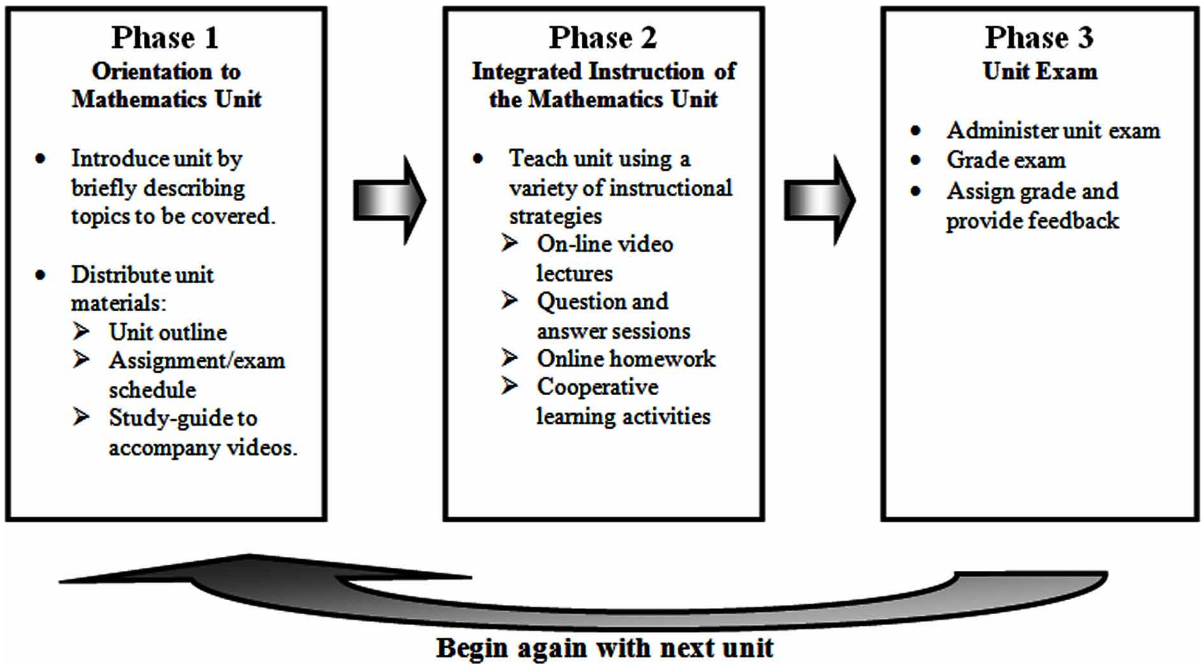
packet of materials that includes an outline of the unit detailing the pace at which material will be covered, a schedule of assignments and activities and their respective due dates, the exam date for the unit, and a "fill in the blank" study-guide for each video lecture to be assigned for the unit.

Phase 2: Integrated Instruction of Mathematics Unit

The second phase begins a cycle of instructional strategies, which include:

- On-line video lectures with accompanying study guide for completion by each student autonomously outside of class;
- A question-and- answer session which takes place during face-to-face class time;
- Online homework assignments, which are assigned for students to complete autonomously outside of class; and
- Cooperative learning assignments, which are assigned for students to complete cooperatively with peers during face-to-face class sessions.

Figure 2. Sequence of phases



A more detailed description of each strategy follows.

On-line video lectures/study-guide: Students are assigned a video lecture to view outside of class. Each video of 10-40 minutes in length includes a lecture explaining a new concept or skill. As students watch the video, they fill in the study guide for that lecture. The study guide helps students take notes by providing a structure that facilitates their organization of ideas. For example, the study guide provides students with partial definitions and places for students to "fill in the blank," boxes for students to copy steps for solving problems, and spaces for students to work problems autonomously. The instructor can use this study guide as evidence that the students watched the video prior to coming to class and may choose to collect the study-guide to check for completion and/or walk around the room documenting student completion on a check sheet. In addition to checking for completion of the study-guide, the instructor can administer a short quiz to check for student understanding of the topic covered in the video lecture. Any points awarded are totaled and contribute to the students' participation grade, which is 10% of their final grade.

Question and answer session: This session enables the student to guide the instruction. Students are given the opportunity to ask questions on material covered in previous videos, face-to-face classes, or on line homework assignments. This strategy gives students the authority to request instruction in areas of issue to them. The instructor notes specific topics where students appeared to be having trouble, so that these areas can be incorporated into future group assignments and/or video lectures to further check for understanding.

Online homework assignments: Students individually complete assignments outside of class. These assignments are online and contain 10-25 questions depending on the topic. Question formats vary from open response to multiple-choice and focus on procedural knowledge such as solving equations. The online homework system offered students various "learning aids." If a student does not know how to solve a problem, he or she may click on one of three buttons for additional help, including "view an example," "help me solve this," and "textbook." "View an example" shows the student a worked problem (step by step) similar to the question being asked of him. "Help me solve this," asks the student to complete individual, successive steps until the problem is solved correctly. If a student enters a step incorrectly, the computer provides feedback and gives the student another opportunity to answer the question. If the student answers again incorrectly, the system tells the student the answer, but gives the student the opportunity to try a different but similar problem. The "Textbook" option takes the student to the section of the textbook related to the question being asked.

The instructor can set due dates for assignments as well as the number of attempts that each student has to answer individual homework questions correctly. The rationale behind setting the number of attempts on homework questions is to provide students with multiple opportunities to work through problems, solicit help when necessary, and re-work problems after receiving help. Each problem in the assignment is scored (some questions have multiple parts so partial credit is given) by the computer and the individual student earns a grade out of 10 points for each assignment. The scores are totaled and scaled to a maximum of 150 points or 15% of the final grade.

Cooperative assignments: Two types of cooperative assignments are implemented throughout the course. Laboratory assignments are implemented in the computer laboratory once a week. In-class problem sets are implemented intermittently during the regular face-to-face class meeting. For laboratory assignments, students work in groups of two or three in a computer laboratory on interactive assignments, which use technology and student activities to emphasize writing and student collaboration. The instructor and two or three "student mentors" (undergraduate and graduate mathematics students) walk around the laboratory to support students and answer questions. With seven computer laboratory assignments, points are awarded for the ability to do and communicate mathematics, as well as students' ability to manage their time and follow directions. The laboratory scores are totaled and scaled to a maximum contribution of 150 points or 15% of their final grade.

In-class problem sets are assigned during regular class time. Students are placed in groups of two to four students. A problem set of 5-10 questions is worked on collaboratively. Students are asked to help each other and refer to their notes before asking the instructor for help. All students must work the problems on a separate sheet of paper; however, the instructor randomly selects the paper to be turned in for the group. Each group assignment is graded and contributes to the students' participation grade or 10% of their final grade.

Phase 3: Unit Exam

The third phase of the teaching model is the administration of the unit exam. In this course there are five units of material and five unit exams. Unit exams are given in the computer laboratory during class time. Each unit exam is worth 80 points. All points from the five unit exams sum to 400 points, which makes up 40% of the students' final grade. In addition to the unit exams, there is a comprehensive final exam worth 200 points or 20% of the students' final grade.

Social System

Typically, college algebra has been taught with the professor as the "sage on the stage," the transmitter of knowledge and students passively receive that knowledge, memorize it, and regurgitate it on an exam (King, 1993, p. 1). The flipped classroom teaching model places the instructor in more of a facilitator's role, so that the students can take center stage. The instructor is responsible for orienting students with each unit, creating video lectures, maintaining the online homework system, supporting a cooperative learning environment, and assessing student performance. Students are responsible for preparing for class by viewing video lectures and completing online homework assignments. In class they must be prepared to ask questions and collaborate with their peers on a variety of assignments.

Principles of Reaction

The reactions of the instructor vary as the instructional components of the course change. When students are engaged in cooperative activities, the instructor's primarily role is that of a facilitator – listening, directing, and helping students work together to find solutions. During a question-and-answer period, the instructor must be prepared to answer questions on a variety of topics as well as re-teach topics with which students are having trouble. The instructor must also monitor student progress in the online homework system and use data from that system to identify areas of difficulty for students.

Students must take responsibility for their learning and must be able to maintain the course schedule suggested by the instructor. They must complete the online homework assignments and view the video lectures when assigned so that they are prepared for face-to-face class activities. During question and answer sessions, students must be prepared to ask questions regarding homework problems or video lectures and during cooperative activities students must be prepared to work with other students and to contribute to the work of their group in a meaningful way.

Support System

The model goes beyond the traditional roles of teachers and students in an effort to facilitate a change in the learning environment; that is, to promote an active learning environment. If the instructor chooses to create his own videos, he will invest a great deal of time organizing, developing, and producing videos for the online environment. For example, in this study, approximately two to three hours was needed to produce 30 minutes of video for one lecture. A skill set including screencasting, uploading, and editing video is essential. Many students are not used to this type of instructional approach, and the instructor must have patience with his students as they transition into an active learning environment. The instructor must consider students' different reactions and abilities to become active participants. Asking questions and working collaboratively with others may make some students uncomfortable but also require some time to develop in students who are not familiar with this form of teaching.

RESEARCH: STUDYING THE COLLEGE ALGEBRA FLIPPED CLASSROOM

Studying the design of the flipped classroom and its implementation will be described along with results and subsequent design revisions to the model. The specific development history of the course will be summarized and results from the pilot testing will be reported, providing a summary of how the course and underlying teaching model developed over time. A research framework provides structure so that the teaching model is continually studied as it is used and serves to establish and build on a knowledge base for users of the model. A research design also provides users of this model with a systematic development approached organized around the development phases of design, implementation, and evaluation over time.

Research Framework

The design and development cycle (Richey & Klein, 2007) provided the framework for the study of the teaching of college algebra across two iterations of the course (Fall Semester 2012, Spring

Semester 2013). The framework provides a way to organize the reporting of design decisions and research findings throughout each of these two cases, as well as a way to facilitate continued and consistent study of the model by its users so that the knowledge base of the model will continue to grow and evolve. According to Richey and Klein (2007), the major phases of the design and development cycle include:

- *Design decisions* for each delivery of the course.
- *Implementation* of the design decisions.
- *Evaluation* of the model.

The report is organized into three sections:

- Methodology,
- Findings, and
- Discussion.

The methodology section includes descriptions of the research design, study participants, data sources and collection procedures, data analysis procedures, and research limitations. The findings section summarizes student learning, the teaching decisions in each case and how those findings impacted the evolution of the flipped classroom teaching model. The discussion section outlines the instructional (direct) and nurturant (indirect) effects of the model on the students, conclusions and implications for future design, implementation, and evaluation of this flipped classroom teaching model.

Research Design

This section describes the design and development of a flipped classroom teaching model in terms of the design decisions, model implementation, and model evaluation across two deliveries of a college algebra course. The following research questions guided this study:

- How did the flipped classroom approach to teaching change over time?
- How does a flipped classroom approach to teaching college algebra affect students' perceptions of their learning of mathematics?

A multiple case study approach was used to report this research in an effort to elucidate how and why the flipped classroom model has changed overtime. Yin (2008) summarized the uses of case studies as a research method and included the following recommendation made by Schramm (1971) that "the essence of a case study…is that it tries to illuminate a decision or set of decisions: why they were taken, how they were implemented, and with what result." Miles and Huberman (1994) define a "case as a phenomenon of some sort occurring in a bounded context" (p. 25). Each case in this study was defined as one course delivery, which was documented in terms of the design decisions, implementation, and evaluation of the flipped classroom teaching model.

Participants: Case one was a fifteen week, fall semester, college algebra course with an enrollment capacity of forty students and case two was a fifteen week, spring semester college algebra course with an enrollment capacity of forty students. Both courses met for 50 minute sessions, five days a week and were taught by the same instructor (i.e. first author). Participants included students enrolled in the sections of the college algebra course being studied. Nothing in the schedule of courses indicated that any of the sections of college algebra were being studied or that any section would be taught differently from any other section listed. Students enrolled themselves in various sections of college algebra based on their QRA (quantitative reasoning assessment) or placement exam score and their personal schedules, not by any pedagogical preference or knowledge of a research study taking place. Prior to the beginning of the Fall 2012 semester, approval from the university's Institutional Review Board (IRB) was granted to implement student surveys and interviews as a means to study the design, implementation and evaluation of the flipped classroom teaching model. Forty-five undergraduate students agreed to participate in the study and signed consent forms. Of those forty-five students, 27 were freshman, 16 were sophomores, 1was a junior, and 1 was a senior. Student majors varied. Participants included forty-five students and the instructor of record. The instructor has taught college algebra seven times over the last 15 years and has taught high school algebra in the public schools for three years.

Data sources and collection procedures: The data sources and collection procedures to study the teaching model are organized around the design and development cycle (Richey & Klein, 2007).

Model design: Data were collected to describe the design decisions for each delivery of the course. Data sources for design decisions included the course syllabus, instructor journal, and a syllabus addition. The course syllabus identified course objectives, instructional materials, assessment, and course sequence as it was defined for all sections of the course. The teacher journal recorded the instructor's observations and thoughts regarding course design.

Model implementation: Data were also collected to describe the implementation of the design decisions. Data sources for the model implementation included a teacher journal and student surveys. The teacher journal recorded daily reflections regarding her thought process throughout model implementation. The journal included reflections regarding classroom observations and summaries of student interactions with other students, the instructor, and/or course materials. Anonymous student surveys were sent to all participants via email two to three times throughout the semester. Each survey consisted of 10 questions. Survey question formats included Likert scale items, as well as short answer/free response items. Questions addressed both student perceptions of their learning as well as their opinions regarding the implementation of the various instructional components, which included lecture videos, face-to-face class time, cooperative laboratories, and online homework assignments.

Model Evaluation: Data were collected to describe student perceptions of their learning and of the instructional approach used to teach the course. Data sources for model evaluation included student surveys, student interviews, and course evaluations. Anonymous student surveys were sent to all participants via email two or three times throughout the semester. Survey question formats included Likert scale items as well as short answer/free response items. Questions addressed both student perceptions of their learning as well as their opinions regarding the implementation of the various course components: lecture videos, face-to-face class time, cooperative laboratories, and online homework assignments. Course evaluations included Likert scale questions (both university-developed and instructor-developed) to record student perceptions of instruction, the instructor, and materials. Student interviews were conducted after the Fall 2012 semester concluded. Students were randomly chosen to represent a range in course performance: one student from each of three grade bands as follows:

- A+ or A,
- B+, B, C+, or C,
- D+, D, F, or W (withdrawal before final grade awarded).

Three students (2 male, 1 female) agreed to be interviewed early in the Spring 2013 semester. One student received an A, one a C, and one a D. Interviews were semi-structured and ranged from 20-30 minutes in length. The interviews were conducted in person, tape-recorded and transcribed. Interview questions targeted student perceptions of the flipped classroom teaching model, how this model impacted their learning, as well as suggestions for improving the course.

Data analysis framework and procedures: Design decisions were analyzed by describing participants, course sequence, learning tasks, instructional strategies, and assessment strategies. Model implementation analyzed student performance and student responses to the varied instructional strategies reflected in the flipped classroom model. Evaluation of the teaching model analyzed student perceptions of their learning and student perceptions of the teaching approach. Data analysis consisted of data reduction or "the process of selecting, focusing, simplifying, abstracting, and transforming the data" (Miles & Huberman, 1994, p. 10) and display of the reduced data so that conclusions can be drawn (Miles & Huberman, 1994). Details of data analysis are described.

Syllabus, syllabus addition, teacher journal: The syllabus provided the course description as well as a description of the components of the course that were to remain intact as the flipped classroom teaching model was designed and implemented. Design decision notes from the teacher journal were collected and categorized by course sequence, instructional strategies, and assessment. A syllabus addition was developed and given to students after the last two unit exams in case one and at the beginning of each unit during case two. The addition was used to identify any changes made to course sequence, instructional strategies, and assessment strategies.

Student surveys: Survey responses were collected online. Mean scores were calculated for Likert scale-type questions and open–ended responses were coded according to student perceptions regarding: the flipped classroom instructional approach, different instructional components (e.g. online homework, video lectures/study-guide, cooperative laboratories, group work, question/answer sessions), and student learning in the class.

Student interviews: Interviews were transcribed and coded based on three categories, student perceptions regarding the flipped classroom instructional approach, different instructional components (e.g. online homework, video lectures/study-guide, cooperative laboratories, group work, question/answer sessions), and their learning in the class.

Course evaluations: Survey responses were collected online. Mean scores were calculated for Likert scale-type questions and open–ended responses were coded according to student perceptions regarding: the flipped classroom instructional approach, different instructional components (e.g. online homework, video lectures/study-guide, cooperative laboratories, group work, question/answer sessions), and student learning in the class.

Research limitations: Multiple data sources were collected and analyzed to check for the agreement of one data source with another. For example, both surveys and interviews were used to provide a picture of how students perceived the flipped classroom model instructional approach as well as their learning. However, the survey response rate was low and made it difficult to generalize results. In future iterations of this research, an effort should be made to increase survey response rate. The surveys could be given during class so that students do not have to complete the survey on their own time.

Personal bias must always be considered when an instructor studies her own teaching. The researcher's personal involvement with the course increased the possibility that recorded observations in the teacher journal highlighted specific incidents while ignoring others. In addition, the instructor of the course was also the interviewer. Although interviews did not take place until after the semester had ended and final grades had been awarded, it is possible that students did not feel as though they could be honest about their thoughts and feeling regarding the course when they were being interview by their instructor. The second author reviewed the student comments' for their trustworthiness, based on her familiarity of the course and students.

Original Design of Course

Math 126: College algebra is a department-coordinated course. There are three variations of Math 126 offered through the department of mathematics at this land-grant university in the eastern United States. A different professor coordinates each variation; however, all three variations (126A, 126B, and 126C) use the same cooperative laboratories and take the same final exam. A summary of the basic structure of each course and the criteria for student placement in each course will follow. In general, all students take the QRA (Quantitative Reasoning Assessment) for placement in a mathematics course. Students are only allowed to take the QRA twice. If they score below 10, students must take the pre-collegiate mathematics workshop (a non-credit course offered by the math department) before they are permitted to enroll in any 126 class.

Math 126A: There are approximately 10-12 sections offered each semester. Each section enrolls up to forty undergraduate students. The class meets five days a week, four days in lecture and one day in laboratory. Students are placed into 5-day College Algebra by scoring 10 out of 25 on the Quantitative Reasoning Assessment QRA (Math Placement Exam) or by taking the pre-collegiate mathematics workshop.

Math 126B: There are three sections offered each semester. Each section enrolls approximately 200 students. The class meets four days a week, two days in lecture, one day in recitation (Q&A), and one day in laboratory. Students are placed into 126B by scoring 11 or 12 out of 25 on the QRA or by taking the pre-collegiate mathematics workshop.

Math 126C: There are three sections offered each semester. Each section enrolls approximately 200 students. The class meets three days a week, two days in lecture and one day in laboratory. Students are placed into 126C by scoring 12 or higher on the QRA or by taking the pre-collegiate mathematics workshop.

The specific goals of all sections of Math 126 emphasize algebraic, graphical, and numerical approaches to study the understanding and use of concepts such as function; mathematical application problems; solving equations and inequalities in one variable using multiple representations; graphing equations and functions; lines, parabolas, and circles; higher order polynomial, rational, radical, absolute value, exponential and logarithmic functions; and systems of equations and matrices. To accomplish course goals, each class incorporates interactive laboratories which use technology and student activities that emphasize writing and student collaboration. Students work in pairs or triads on the laboratories and in class exercises in order to develop mathematical communication skills.

The version of college algebra studied for the purpose of this chapter was Math 126A: 5-day college algebra. In each of the two cases, 40 students met in an auditorium classroom Monday, Tuesday, Thursday and Friday. The classroom was equipped with 40 student seats and instructional aides, and included one computer that can project onto a screen and several rolling chalk boards. The class met each Wednesday in a computer laboratory where students worked cooperatively on interactive laboratories that focused on conceptual understanding and application. The computer laboratory can accommodate 120 students and is equipped with 120 student computers and a podium with a computer for the instructor. There are several screens positioned around the laboratory so that the instructor can project his/her screen throughout the laboratory. Two sections of Math 126A meet in the laboratory at the same time; however, the two sections are separated so that when students work cooperatively, they are working with students that are in their face-to-face class.

Components of Math 126A common to all 12 sections:

- **Participation:** 100/1000 points. Students may earn up to 100 participation points. Each instructor may choose to use sign-in sheets, short participation quiz/work sheets, and/or other activities to generate participation points.
- **Online Homework:** 150/1000 points. Students are required to complete homework assignments online. Homework assignments correlate to the sections covered in the textbook.
- **Laboratories:** 150/1000 points. There are seven computer laboratory assignments. Laboratory assignments should be completed with a partner in the laboratory during scheduled laboratory time. Laboratory points are awarded for the ability to do and communicate mathematics as well as the ability to manage time and follow directions.
- **Exams:** 400/1000 points. There are five tests given throughout the semester on Wednesdays in the laboratory during class time, each is worth 80 points. The exams include pencil-and-paper questions and online multiple-choice questions.
- **Final Exam:** 200/1000 points. There is a comprehensive final exam given at the end of the semester. The same final exam is given to all variations of Math 126.

Findings

Case 1: Fall 2012

Case one was a 15-week course offered during the Fall 2012 semester. Forty students were enrolled in the class, which met five days a week for 50 minutes each day.

Design

The Math 126A course coordinator was supportive of the initiative to incorporate a flipped classroom pedagogical design into Math 126A, however, Math 126A is a department coordinated course. The coordinator decided that the major components of the course should be the same for all sections of the course. Any grades that were to be collected specific to video lectures and accompanying assignments could only be reflected in the course component of student participation (100/1000 points). All students were to use the same online homework assignments and interactive computer laboratories and exams.

As all components of the course were to remain intact, the challenge was to design a flipped classroom approach that incorporated both video lectures and online homework assignments. Traditionally, a classroom flip involves lectures, which are assigned for students to view at home. Homework assignments are assigned and completed during class time. Since the required online homework assignments could not be completed in class (because the class does not meet in a computer laboratory), the design had to be modified to use both video lectures and online homework while still affording students face-to-face class time for non-traditional learning activities. All components of the course remained intact, but videos were assigned as homework approximately two times per week and brief one-two questions quizzes were administered during the first five minutes of class when a video was assigned for homework the night before.

Implementation

The first implementation of this flipped classroom approach was a hybrid, a mix of a traditional lecture and a flipped classroom. Since the instructor/researcher was developing and producing videos while teaching the course, it was not possible to produce a video for every section of material. Sections were strategically chosen for video production. Two sets of videos were developed and implemented each week. As documented in the teacher journal, approximately two to three hours were required to produce 30 minutes of video. An outline suggesting the pace of instruction was given to each instructor at the beginning of the semester. The outline provided a day-to-day schedule suggesting the sections of material to be taught each of the five days the class met. Some of the longer sections of material to be taught were allotted two days on the schedule. The instructor/researcher chose these sections for video production, so that the section could be started in class through a class lecture and finished at home using a video lecture, freeing up the second face-to-face meeting for something more engaging for the students (i.e. group work or question/answer). Typically, 30 minutes of video was produced for one lecture using a screencast product. Videos were uploaded for students to watch online. Since the online site required videos to be under 15 minutes in length, some sections required the production of multiple videos. For example, for section 6.1 Composite Functions, one 14 minute video was produced, but for section 6.4 Logarithmic Functions, three videos were produced (8, 14, 8 minutes). Periodically, the instructor administered a one or two question quiz at the beginning of class to assess who watched the videos and to check for understanding of the material taught on the videos.

Multiple components of the course (participation, online homework, laboratories) were integrated into each week of instruction. An example week was designed as follows:

Monday: Face-to-face: group work (6.1)
Homework: online homework 6.1
Tuesday: Face-to-face: Lecture 5.1 and R.6
Homework: online homework 5.1 and R.6
Wednesday: Laboratory-Quadratic Functions
Homework: watch Videos (5.2)
Thursday: Face-to-face: Q&A (5.1 and 5.2)
Homework: online homework 5.2
Friday: Face-to-face: group work (5.1, R.6, 5.2)
Homework: watch Videos (5.3)

Group work was assigned, collected and graded, and the grade was applied to the participation component of the course (10% of final grade). Cooperative laboratory worksheets were collected and graded, and the grade was applied to the laboratory component of the course (15% of final grade). Participation points were awarded to all students that attended on designated question and answer sessions. Online homework assignments were graded electronically, and the grade was applied to the online homework component of the course (15% of final grade).

Evaluation

Nine students responded to an anonymous survey administered online during the fifth week of the semester. When asked to rank order the components of the course (online lecture videos, face-to-face class time, computer laboratories, and online homework assignments, quizzes), six out of nine students ranked face-to-face time as the most helpful, while three of the nine ranked the videos most helpful. Five of nine students ranked videos as second most helpful and three of nine ranked face-to-face second most helpful. All nine respondents said that they were satisfied with the design of the online videos and all nine respondents said that they were satisfied with the use of face-to-face time. Students were asked to respond to four open-ended questions. The questions included the following: How do you feel about watching lectures online at home and working on problems in class? What suggestions do you have that might make the videos more helpful? What suggestions do you have that might make the face-to-face time more helpful? What would have helped you better prepare for the last test? Two themes emerged due to the frequency of their occurrence throughout the open-ended responses: the opportunity to self-pace and the freedom to ask questions.

Opportunity to self-pace: Students felt that the videos provided an opportunity for them to slow the instruction down to meet their individual needs. For example, one student wrote that “I feel the on-line videos are extremely helpful. It’s nice to sit down and take it at my own pace." Another student wrote: "It [videos] gives me the chance to learn the material at my own pace." Students also liked being able to play, rewind, and re-play the video lectures. One student wrote: "I feel that watching the videos at home helps me learn because I can stop and replay the video so that it reworks the problem in case I didn't understand the first time."

Freedom to ask questions: Students also felt that the videos afforded them the opportunity to ask questions during the face-to-face meetings. For example, one student wrote the following: "I enjoy this because the class has time to get all of [our] questions asked instead of people being left confused." Another student wrote that "I can bring in problems that I didn't understand and she can explain them to me face-to-face."

When asked for suggestions for improving the instruction of the class, students suggested using different colored pens throughout the videos and providing deeper explanations in the videos. One student wrote that the videos were helpful but "extremely time consuming."

The survey was repeated during week 10. Six students responded to the survey. Responses to the open-ended questions supported the same two themes as the first survey, including the opportunity to self-pace and freedom to ask questions. Regarding pace, one student wrote: "I can continue to go over the videos until I fully understand what they're teaching me. Another student wrote, in regard, to asking questions: "we get to choose the problems that are troubling us and do them [in class face-to-face]," while another student wrote that "I wish there was a video for every section."

At the end of the semester university course evaluations were administered anonymously online. Ten students responded. When students were asked to rate their learning in the course (very little, some, more than average, quite a lot), six rated their learning as "quite a lot" and four rate their learning as "more than average." When asked if the video lectures helped them to understand the material, eight students responded "always," one responded "frequently," and one responded "rarely." The overall rating of the course was 4.7 out of five points.

Three student interviews were conducted during the spring 2013 semester in an effort to gain deeper insight into student perceptions regarding their learning with respect to the instructional approach used in the course. Based on their high frequency of occurrence throughout the interview transcripts, three themes were identified: interconnectedness of instructional components, more time for student questions, and instructor qualities.

Interconnectedness of instructional components: Although one student may favor one instructional strategy over another, all three students mentioned the various components worked together to foster student leaning. For example, when asked, "Which component was most helpful in terms of helping you learn?" one student said, "You can't really take one or the other, because yes, you have the videos and it's like having class at home, but then if you don't understand any of it, you need the class to ask. So they kind of go hand and hand. You can't have one without the other." Another student who earned a D in the course and was retaking the class with another instructor at the time of the interview said with regard to the flipped approach, "I definitely learned more, definitely had a better understanding with the group work, the videos, the study-guides, I learned it, it was all right there, it was up to the students still, but you provided all that the student needs to be successful."

More time for student questions: Another emergent theme was that more time was allotted for student questions. Students frequently responded that they liked being able to ask questions in class regarding material with which they that they were having trouble. One student said that "In a normal class, the teacher is just preaching at you…with the videos you can watch them and then you ask questions…you had a class where you could actually ask questions."

Instructor qualities: Instructor qualities emerged as a third theme during student interviews. The interview transcripts revealed that students felt that the flipped classroom approach could only be as effective as the instructor using it. For example, when asked if he would recommend a flipped college algebra class to friend over a traditional class one student said, that he would only if he knew that the instructor he had would teaching the class. He went on to say that "The way [she] set up the class, it was enjoyable, I felt that it was not hard to succeed, all of the tools were there, it was interesting, a good time, she interacted with the students." Another student said, "She was so enthusiastic, so helpful, so nice…I feel that personality really does matter when your teaching because it effects people." Table 1 summarizes case one findings.

Case 2: Spring 2013

Case two was a 15 week course offered during the spring 2013 semester. Forty students were enrolled in the class. The class met five days a week for 50 minutes each day.

Design

Design decisions for case two were the same for case 1 as the course coordinator requested that all components of the course remained intact. In addition to the videos implemented in case one (approximately two per week), new videos were produced and implemented throughout the semester. Videos were available for nearly all sections of material to be covered throughout the course. Also, various "learning aids" offered inside the online homework package were made accessible to students. For example, if a student did not know how to solve a problem on the online homework assignment, they were able to click on one of three buttons for additional help, the buttons were "view an example," "help me solve this," and "textbook." "View an example" would show the student a worked problem (step by step) similar to the question being asked of them. "Help me solve this" would ask the student to complete individual, successive steps until the problem is solved correctly. "Textbook" would take the student to the section of the textbook related to the specific question being asked.

Table 1. Case 1: Summary of findings

Design: ● Develop and assign at least two videos per week. ● Write and administer one to two question quizzes in class after video lecture assignments. ● Assign online homework on nights when no video lecture is assigned. ● Develop and assign group work at least once per week. ● Facilitate cooperative laboratories activity once per week. ● Hold question and answer sessions in class at least once per week.
Implementation: ● Longer sections of material were strategically chosen for video development. ● Two to three hours were required to produce 30 minutes of video. ● Videos were uploaded to an online site for students to view. ● One to two question quizzes were administered in class after video lecture assignments. ● Group work was collected and graded. ● Cooperative laboratory worksheets were collected and graded. ● Participation points were awarded to students who attended in-class question and answer sessions.
Evaluation: ● Students felt that the videos provided them an opportunity to self-pace instruction. ● Students felt that the videos gave them more time to ask questions in class. ● Students felt that the instructional components of the course worked together to foster their leaning. ● Students felt that the teaching approach could only be as effective as the teacher using it.

Implementation

Since a video was available for use with the instructions of most sections of material, a "truer" flipped classroom approach could be implemented in case two. Multiple components of the course (participation, online homework, laboratories) were integrated into each week of instruction. An example week was designed as follows:

Monday: Face-to-face: group work (6.1)
Homework: Watch Videos R.6 and 5.1
Tuesday: Face-to-face: Q&A (R.6 and 51)
Homework: Watch Videos 5.2 (part 1 and 2)
Wednesday: Laboratory-Quadratic Functions
Thursday: Face-to-face: Q&A (5.2)
Homework: Watch Videos 5.2 (part 3)
Friday: Face-to-face: group work (5.1, R.6, 5.2)
Homework: Watch Videos (5.3)

Assigned group work was collected and graded and the grade was applied to the participation component of the course (10% of final grade). Cooperative laboratories were collected and graded. The grade was applied to the laboratory component of the course (15% of final grade). Participation points were awarded to all students that attended class on designated question and answer sessions. Online homework assignments were graded electronically and the grade was applied to the online homework component of the course (15% of final grade).

Reflections documented in the teacher journal suggested that the instructor made the decision to create "soft" deadlines for online homework assignments. All online homework assignments were set at the beginning of a unit and the due date was set for all assignments specific to that unit for the morning of the unit test. This decision was made in an attempt to accommodate individual student schedules and provide students the opportunity to ask questions regarding homework assignments and subsequently the opportunity to revisit assignments and make corrections. Students took responsibility to complete the online homework assignments after the section was covered via video, question/answer sessions, or in-group work.

A calendar (syllabus addition) was given to students at the beginning of each unit to specify when to watch videos, formats of each face-to-face sessions, and a suggested pace for completing the online homework.

Evaluation

Nine students responded to an anonymous survey administered online during the fifth week of the semester. When asked to rank order the components of the course (online lecture videos, face-to-face class time, computer laboratories, and online homework assignments, quizzes), four out of nine students ranked face-to-face time as the most helpful, and four students ranked the online homework assignments as most helpful. No one ranked the videos most helpful. On the other hand, six of nine students ranked videos as second most helpful, one ranked the online homework as second most helpful and one student ranked face-to-face second most helpful. All nine respondents said that they were satisfied with the design of the online videos and all nine respondents said that they were satisfied with the use of face-to-face time. Students were asked to respond to four open-ended questions. When asked about their feelings regarding the flipped classroom instructional approach, only one theme emerged due to the frequency of its occurrence throughout the open-ended responses and this theme was the opportunity to self-pace.

Opportunity to self-pace: Students felt that the videos provided an opportunity for them to slow the instruction down to meet their individual needs. For example, one student wrote, "I greatly enjoy being able to review lecture material at my own pace via the online lecture videos. It allows me to clarify any questions I may have and provides motivation to be prepared for the next day's activity."

In addition to the opportunity to self-pace theme, students made several different suggestions regarding the flipped classroom approach. The suggestions included the following: provide more examples for students to try on their own along with solutions during the videos, give general explanations regarding course material rather than focus on specific questions during the face-to-face meeting, and provide a study-guide with solution set prior to the unit test.

The survey was repeated during week 10 and five students responded. When students were asked to indicate their level of agreement with the following statement, "The lecture videos that I watched outside of class helped me learn the material," all five students agreed. When they were asked similar questions regarding the face-to-face sessions, all five students agreed that the face-to-face sessions helped them learn the material. When students were asked to rank order the components of the course with regard to their helpfulness, students either chose face-to-face class session (four students) or online homework (one student). Few students thoughtfully responded to the open ended questions and as a result no themes emerged. One student responded "I think the face to face class time is effective when learning the material" and another said "I think the videos are fine as they are." See Table 2 for a summary of case two findings.

Cross-Case Analysis

Design and Implementation

Modifications across both cases included the following:

- A video was produced and implemented for every section of material.
- Soft deadlines were introduced for the online homework assignments, allowing students to complete assignments at their own pace and to rework problems after they received help from the instructor.
- Learning aids from the online homework package were made accessible to students. For example, if a student did not know how to solve a problem on the online homework assignment, they were able to click on one of three buttons for additional help, the buttons were "view an example," "help me solve this," and "textbook."
- A calendar (syllabus addition) was distributed to students at the beginning of each unit, providing due dates videos/study-guides and suggested pacing for online homework assignments

Table 2. Case 2: Summary of findings

Design: • Develop at least two videos per week to add to existing video library. • Assign videos from case one and newly developed videos so that most sections of material have an accompanying video lecture. • Assign online homework. • Enable learning aids offered inside the online homework system. • Develop and assign group work at least once per week. • Facilitate cooperative laboratories activity once per week. • Hold question and answer sessions in class at least once per week.
Implementation: • Soft deadlines were introduced for the online homework assignments. • A calendar detailing the pace of the course and assignment due dates was distributed at the beginning of each unit. • Group work was collected and graded. • Cooperative laboratory worksheets were collected and graded. • Participation points were awarded to students who attended in-class question and answer sessions.
Evaluation: • Students felt that the videos provided them the opportunity to self pace instruction.

Evaluation

Student's perceptions of their learning via the Flipped Classroom Teaching Model across both cases are summarized.

Overall teaching approach: When students were asked to rate their overall learning in the course on the university course evaluations, the mean rating was 4.6 out of five. Students attributed their learning to course components working together. For example, one student said, "Sometimes when doing my homework I did not know what to do so, I would refer to my notes and still be confused, but then, I would refer to the videos and watch you [the teacher] do the steps and then go back to the homework and know how to do it."

Freedom to ask questions: Another student described why he felt that he learned more in the flipped classroom environment rather than a traditional environment, "It's just with a normal class, the teacher is just preaching at you, at least that is how it feels, but with the videos, you can watch them and then ask questions, [face-to-face time] was dedicated to what you didn't know, so you learned, it wasn't a teacher just teaching everything and saying they think you know something you don't, you have time to ask about what you don't know." Students felt that being able to ask questions helped them learn because face-to-face class time was devoted to their satisfying their individual needs.

Opportunity to self-pace: Students also felt that they learned more watching video lectures at home because the online lectures gave them the opportunity to work at their own pace. One student wrote that "Watching the lectures online at home help me learn the material because I can continue to go over the videos until I fully understand what they're teaching me."

Discussion

The purpose of this study and chapter was to describe the design and development of a flipped classroom teaching model in terms of the design decisions, model implementation, and model evaluation across two deliveries of a college algebra course. This chapter illustrates how the flipped classroom approach to teaching changed over time and how a flipped classroom approach to teaching college algebra affected students' perceptions of their learning of mathematics.

The first research question addressed in this chapter was: How did the flipped classroom approach to teaching change over time? The instructor/researcher developed videos while teaching both cycles of the course. Because she was able to reuse many of the videos developed during the first iteration, the number of videos available to students during the second iteration nearly doubled. Videos were assigned to students approximately two times per week during case one and nearly four times a week in case two. As a result, the homework expectation increased for students during the second iteration of the course. During case two, students were assigned video lectures to view at home and online homework assignments to complete at home almost every night. Soft deadlines for the online assignments were introduced to allow students to complete the online homework assignments at their own pace. Learning aids in the online homework system were made available to students during case two. The learning aids provided immediate assistance to students working on homework assignments by providing a worked example, a step-by-step solution, or the passage in the textbook that addresses the types of exercises presented in the assignment. To help students stay organized, a calendar (syllabus addition), which provided due dates and suggested pacing for learning tasks and assignments, was distributed at the beginning of each unit.

The second research question addressed in this chapter was: How does a flipped classroom approach to teaching college algebra affect students' perceptions of their learning of mathematics? Findings reported in this study are preliminary and subsequent iterations of the design and development cycle (Richey & Klein, 2007) are necessary to document a clearer picture of the flipped classroom model and its impact on student learning. However, student survey responses and interview results suggested that this teaching model improved student perceptions of college algebra. These findings confirm results from Stage and Kinzie (2009) who found that students are more enthusiastic with respect to learning when they are taught by innovative instructional techniques.

Students felt that the online instructional videos provided an opportunity to control the pace of instruction. For example, one student wrote, "I greatly enjoy being able to review lecture material at my own pace via the online lecture videos. It allows me to clarify any questions I may have and provides motivation to be prepared for the next day's activity." Self-regulated learners view learning as a process that they can control, that is; a process that they have ownership of, in addition; self-regulated learners take responsibility for what they know and have the strategy skills to learn what they do not know (Zimmerman, 1990). The flipped classroom model enabled students to take control of the learning process.

In addition to controlling the pace of instruction, students perceived the flipped classroom model as student-centered. Students felt that having the freedom to ask questions helped them learn because face-to-face class time was devoted to satisfying their needs. One student said, "It [face-to-face time] was dedicated to what you didn't know, so you learned, it wasn't a teacher just teaching everything and saying they think you know something you don't, you have time to ask about what you don't know." Garrison (2010) encouraged teachers to design instruction that elicits a student's need to further his understanding and deepen his knowledge. The flipped classroom teaching model can be used to elicit this need by providing student's an opportunity engage in the learning process and the freedom to ask for help.

Some findings differed from case one to case two with respect to emergent themes from student surveys. In case one, students overwhelmingly cited the freedom to ask questions during class as one of the major benefits to the flipped classroom approach, however; this theme did not emerge during case two. One possible reason could be the learning aids made available on the online homework system in case two. Perhaps, students asked fewer homework questions in class because they used the help buttons in the online homework system. One concern might be that students are simply memorizing a procedure rather than learning the underlying mathematical concepts when using these learning aides.

Another possible reason that students asked fewer questions in class during the spring semester might be that students were not keeping up with the online homework or video assignments, and as a result were not prepared to ask questions in class. Students were only asked to watch videos twice a week during case one but asked to watch videos nearly every night in case two; therefore, assigning online homework and video lectures as homework may be too much for students to complete at home on their own.

Model Effects: According to Joyce, Weil, and Calhoun (2009), the effects of any learning environment can be instructional (direct) or nurturant (indirect). Since student learning was not evaluated in this study (to be addressed in subsequent deliveries), the instructional effects cannot be legitimately articulated in this chapter. However, the nurturant effects of the Flipped Classroom Teaching Model, which have a bearing on students' motivations and attitudes towards learning algebra, are discussed.

Nurturant effects: Two nurturant effects surfaced from the flipped classroom teaching approach. First, students appeared to exhibit better self-regulative skills. When asked about the flipped classroom teaching approach, one student said, "It gave you the tools to learn…it was up to the students, but you provided all that the student needs to be successful." The flipped classroom teaching approach led some students to take responsibility for their learning. In a course known for large numbers of students earning D's, F's or withdrawing from the course and poor student attitudes, it was remarkable to hear students taking the blame for their own lack of effort. When asked "What would have helped you better prepare for the last test?" several students took responsibility for themselves. For example, one student said, "Mainly extra studying. I think we are given enough resources and practice that we should be responsible for the outcomes." Another student said: "Low test scores (like my own) were brought on by the student. We have everything we need."

Another nurturant effect appeared to be that students began to relate success to learning and not just good grades. Goal orientation theorists advocate interventions that design classroom learning environments such that achievement is defined as mastery-oriented rather than performance-oriented (Ames & Archer, 1988). For example, a goal-oriented approach to learning focuses achievement on mastering a task, the learning process, and self-improvement whereas a performance-oriented approach to learning emphasizes normative standards or getting the highest grades. Ames and Archer (1988) found that when a mastery goal-oriented approach was perceived by students, students reported using more learning strategies, enjoying their class, and a willingness to tackle challenging problems. The flipped classroom teaching approach provides the instructor the opportunity to focus the learning environment on mastery-oriented learning rather than performance-oriented learning.

SUGGESTIONS AND RECOMMENDATIONS

It is important to continue the design and development of the flipped classroom teaching approach as a systematic approach prompts the instructor/researcher with being clear on learning outcomes and teaching decisions, as well as identifying data sources that answer research questions. Subsequent cases and delivery of the college algebra course using the flipped classroom model will document student learning and require that across the design and development cycle, student learning is analyzed. Although the two case studies reported in this chapter suggest some interesting findings, further study is necessary.

Assigning video lectures and online homework assignments may be too much for students to complete at home autonomously and some teaching adjustments may be needed. Since the online homework is a component of this departmental course and must remain intact, sections of course material could be re-evaluated to determine which sections of material are most conducive to flipping. The flipped classroom teaching strategy may not need to be implemented daily, but strategically during the week so that some face-to-face class sessions can be devoted to engaging activity.

Suggestions for future consideration include the following: re-assessing the use of the learning aids in the online homework system, re-evaluating the amount of homework given to students on a daily basis, and considering whether some topics are more conducive to flipping than others.

FUTURE RESEARCH DIRECTIONS AND CONCLUSION

The flipped classroom teaching model shows promise for the learning of college algebra. Results from the two case studies suggest that students feel as though they can control the learning environment. Students liked that their questions were the focus of face-to-face class time and that they could view video lectures at their own pace, or outside of class, at a time convenient for them. These student perceptions may be crucial conditions for students to engage and ultimately to master concepts and applications.

Student learning was not evaluated in this study. The instructional effects of a flipped classroom teaching model for college algebra will be addressed in subsequent iterations of the course and could include the understanding and using functions; mathematical application problems; solving equations and inequalities in one variable; using multiple representations; graphing equations and functions; lines, parabolas, and circles; higher order polynomial, rational, radical, absolute value, exponential and logarithmic functions; systems of equations and matrices.

This chapter documents the challenges of designing, implementing, and evaluating a flipped classroom teaching approach. The design and development cycle forces one to be more systematic in teaching decisions and to evaluate during the teaching the impacts of the teaching. The case studies provided examples of preliminary designs that positively impacted student's perceptions of their learning. This research study can help guide instructors who are considering using the flipped classroom teaching approach in their own classrooms and the challenges that such an approach requires of a college instructor.

KEY TERMS AND DEFINITIONS

Active Learning: Learning that involves active student participation in classroom activities.

Blended Learning Environment: A learning environment that utilizes both online and face-to-face learning activities.

Cooperative Learning Activities: Activities designed to promote student collaboration to reach a common goal.

E-Learning: Learning that involves student use of electronic and often online resources.

Flipped Classroom: A teaching strategy where lectures (which typically take place inside the classroom) are assigned as homework so that class time can be used for engaging activities.

Inverted Classroom: A synonym for flipped classroom.

Screencasts: Screencast or screen capture is the digital recording of any activity taking place on the computer screen.

This work was previously published in Promoting Active Learning through the Flipped Classroom Model edited by Jared Keengwe, Grace Onchwari, and James N. Oigara, pages 47-70, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

Chapter 30
Blended Learning Support for Undergraduate Students' Research and Writing Skills Development

Asako Yoshida
University of Manitoba, Canada

ABSTRACT

In this exploratory study, a subject librarian and a writing instructor investigated the potential of designing blended learning around research paper assignments in the context of two foundational courses in the Faculty of Human Ecology at the University of Manitoba, Canada. The objective was to explore alternative, more embedded learning support for undergraduate students. The significance of blended learning support was situated in the broader literature of the teaching and learning practices in higher education. In this case study, descriptions of blended learning support for facilitating student learning, and of the main barrier to its implementation are provided. Based on what was learned in the exploratory study, the chapter provides working guidelines for designing and developing blended learning support, mainly drawing from Butler and Cartier's (2004) research on academic engagement.

INTRODUCTION

The on-going development in Information and Communications Technology provides affordances to explore the designing of more meaningful and student-centered learning environments in higher education. The idea of developing student-centered learning environments can be applied to supporting undergraduate students' research and writing skills in many undergraduate programs. Blended learning, "the thoughtful integration of classroom face-to-face learning experiences with online learning experiences," (Garrison & Kanuka, 2004, p. 96)[1] has the potential to be an alternative to the primarily lecture-based traditional writing-intensive courses in many undergraduate programs. The project that will be discussed in this chapter was conceived as a learning project and initiated by a subject librarian and a writing instructor, to explore an alternative more integrated model, by

DOI: 10.4018/978-1-4666-8246-7.ch030

embedding blended learning in a specific course context in collaboration with course instructors. The project involved designing blended learning around research paper assignments in the context of two different foundational undergraduate courses in the Faculty of Human Ecology at the University of Manitoba in Canada. This case study explores blended learning—primarily focusing on its pedagogical issues—as the means for offering students alternative learning environments that may be more conducive to supporting and scaffolding development of their research and writing skills. Because this was initiated neither by the course instructors nor by the faculty-level planners, there was a question of the extent to which the course instructors would welcome the collaboration. Furthermore, this study was not intended or meant to redesign the courses that were essentially conceived and designed as traditional, face-to-face classes. The study, however, started with the intention of the librarian and the writing instructor to investigate a better way of supporting the development of students' research and writing skills with an open attitude of "see what's going to happen." The project thus became an exploratory study because we looked for the opportunity to enhance student learning while we prepared to make necessary adjustments to honor the original course syllabi and the course instructors' teaching. The students who are coming into higher education are increasingly diverse not only in their research and writing skill levels, but also in their prior experiences before their entrance to the undergraduate programs. We were interested in the potential of blended learning support to broaden the learning opportunity for an increasingly diverse undergraduate students body.

The exploratory study was shaped largely in response to two different course circumstances and resulted in two different outcomes: in the first course, the blended learning support aspects of the course integrated well into the rest of the course while the integration did not work well in the second course. The objectives of this chapter are:

1. To situate the original intention of the exploratory study in the broader literature addressing the teaching and learning practices in higher education.
2. To present a case study of blended learning support by comparing and contrasting the two different course circumstances.
3. To describe student learning experiences from the exploratory study using the results of the surveys and semi-structured interviews with student volunteers as well as the observations and insights that emerged from the study.
4. To describe the key potential of blended learning support in facilitating student learning and to offer designing guidelines, drawing mainly from Butler & Cartier's (2004) and Nelson's (1990) research.

BACKGROUND

How the learning opportunities are created or arranged for students in higher education are traditionally dictated by the specific roles or service functions assigned to teaching faculty, librarians or writing instructors, respectively. Also there is some variation in how the learning support functions on campus are organized, whether they are managed under one administrative unit or managed separately under multiple administrative units.[2] The course instructor has authority over the course content, while librarians and writing instructors are often asked to parachute into the class to address the information literacy skills or writing skills. Alvarez (2007) points out the "institutional disconnect" inherent in the traditional support model in which librarians and writing instructors support research and writing skills of students "in parallel lines" (p. 27) – by separating students supports into the pedagogy of research and the pedagogy of writing. Although it is traditional to teach research and writing skills as two separate sets of skills within higher education, both skills are intricately connected and interwoven around a given academic task. We thus embarked on an exploratory study to investigate the potential for implementing blended learning support as a means to create an alternative learning environment in which undergraduate students can assess the academic task at hand more productively, and in which "situated learning" (Lave & Wenger, 1991) can take place.

Teaching and Learning Environment for Research Paper Assignments

The initial attraction to the notion of blended learning emerged from the experiences of the subject librarian who was offering a library session for a long-established foundational course in the Faculty of Human Ecology. She came to note, after supporting the course for many years, that the description of research paper assignments and the instructions given in the course were not sufficient to guide students. The assignment was to develop and construct students' own "definition" of Human Ecology, drawing from course readings and other academic sources. The Faculty of Human Ecology offers a number of different undergraduate programs in reference to the broader highly interdisciplinary area of study identified as "Human Ecology." The assignment was, in fact, a reflective paper for students to shape and define their own perspective about Human Ecology, drawing from their own personal aspiration or orientation to the particular program area they were individually pursuing in the Faculty. They were asked to do this by incorporating academic sources they located in the literature. Many students, however, often caught up in the words, "the definition" included in the assignment sheet, were mistakenly guided to look for some "official" definition in the literature without taking into consideration their own perspective or experience.

The particular instance of undergraduate research paper assignment was described as an example. In general, however, it seems a common practice in higher education to rely mainly on the explicit descriptions of research paper assignments for everyone: instructors, students and support professionals alike. It had been a regular practice for the subject librarian to discuss the nature of research paper assignments with the course instructors before conducting her library sessions. In the past, the discussions with the foundational course instructors about research paper assignments were often limited to simply referring to the explicit descriptions of the assignments provided in the assignment sheets. Although students seemed to need some fundamental support in understanding their assignments better, this practice inherently emphasized the end products as opposed to the learning processes involved in producing the final papers. Brown, Collins, and Duguid (1989) view this common practice in higher education as the result of assuming the traditional pedagogy of didactic education: "a separation between knowing and doing, treating knowledge as an integral, self-sufficient substance, theoretically independent of the situations in which it is learned and used" (p. 32). Entwistle, McCune and Hounsell (2003) indeed confirm the common experience of lower undergraduate students: "Much of the academic discourse remains implicit within the early years of undergraduate students, and so students can be left confused about what exactly is being required of them to earn good grades" (p. 4). The traditional practice in higher education seemed almost designed to fail students at the time when they can be guided to build the foundation for their future studies.

What are the other barriers to make more productive learning experiences around research paper assignments for undergraduate students? The Canadian study of all undergraduate writing assignments given during one school year at one small, liberal arts college attests to the difficulty of students in interpreting what exactly is expected in the writing assignments that are identified as "papers" or "essays" (Graves, Hyland & Samules, 2010). The primary difficulty associated with the undergraduate written assignments, according to the study, is the labeling of diverse tasks included under the category of written assignments. They found that "definitions and meanings across the many different labels are unlikely to be consistent" (p. 310). More importantly, although the explicit information about the "paper" or "essay" task is provided in the syllabus or assignment sheet, students are often not well versed in interpreting those, nor are they purposefully directed to the implicit and social-contextual dimensions of the academic task definition (Hadwin, 2006; Haggis, 2007). These "hidden" aspects of the assignment are often left out of the syllabus or the assignment sheet for discussion. Although such information may be provided face-to-face in the class meetings, without clear guidance or support available, students tend to interpret what is expected in "research papers" or "essays" in their own terms with their limited experiences (Bereiter & Scardamalia 1987; Gordon 1990; Hammann 2005; Perry, 1998).

Guiding students through the complex processes involved in completing higher education research papers poses a challenge for many instructors. Elanders et al (2012) observe that it is not unusual for course instructors to experience difficulty in specifying what constitutes good student writings. Haggis (2006) argues that the complex processes "can only be described, discussed, compared, modeled and practiced" but "cannot be 'delivered' " (p. 532). As an example, she explains the importance of analyzing with students what an essay question is addressing by discussing its complexity from various angles "rather than closing it down, or predetermining the student's answer" (p. 532). In response to the common problem of making the complex academic task a more productive learning experience for undergraduate students, Bass and Eynon (2009) provide a powerful impetus for adopting new pedagogies in higher education: making the invisible visible for student learning. Bass and Eynon refer to the notion of "expertise" to explain the pedagogical advantages of new media environments in higher education. They emphasize that the new emerging pedagogies associated with the use of the new media allow novice learners to explore and experience intrinsic and intermediate processes with intricate layers of learning as practiced by the experts. They also argue that the new emerging pedagogies associated with the use of new media in turn creates the opportunity for the novice learners to incorporate the accompanying dispositions of the experts as their own.

The Approach to Facilitating Information Literacy

When students are not connected appropriately to the tasks at hand in a research paper assignment, the tasks will not lend themselves to facilitating the students' information literacy skills. The librarians as a professional group refer to the Information Literacy Competency Standards for Higher Education (ACRL, 2000) to guide and facilitate students' information literacy skills. However, following Lava and Wenger (2009), any general abstract presentations pertaining to human skills in the form of principles or standards, such as the ACRL Standards, are "meaningless unless they can be made specific to the situation at hand" (p. 33). According to them, these Standards are akin to "so-called general knowledge" and they have "power [only] in specific circumstances" (p. 33). In other words, we can only facilitate students' information literacy skills as they work through assignments to understand and address the tasks that they are being expected to learn in a given course context. Only in an actual working context can students assess the relevancy and use of the information sources they found. The approaches taken by Zamel and Spack (1998) in understanding how students acquire academic literacies may be useful in situating students' information literacy skills and writing skills development. Drawing from research on second language acquisition, Zamel and Spack argue that academic literacies also have to be perceived "not as an end in itself, but rather as a means for understanding and constructing knowledge" (p. x). The important point would be for students to be able to engage in meaning-making of their own to address the subject matter or the topic they are studying. Information literacy has to be part and parcel of students' intellectual processes. Facilitation of the information literacy skills as identified in the Competency Standards, therefore, should not be left as purely technical skills to be measured. Instead, facilitation of information literacy has to be situated in "student-centered learning environments where inquiry is the norm, problem-solving becomes the focus, and thinking critically is part of the process" (ACRL, 2000, para 14). Furthermore, the learning in higher education has to take place in the academic practice of a chosen discipline. This means to learn "how to do the learning in that subject—how to think, question, search for evidence, accept evidence, and put evidence together to make an argument that is acceptable in that discipline" (Haggis, 2006, p. 532).

Student Approaches to Learning Research and Writing Skills

What is the evidence in the literature addressing how students are coping or adjusting to the new set of learning strategies that is required for completing undergraduate research paper assignments? The studies investigating how students approach research paper assignments attest to the importance of appropriate guidance for students to complete their writing assignments. Limberg (1999), for example, identified three different understandings of information seeking and information use among high school seniors who worked on the identical research assignment. Her research indicated that their different approaches to the assignment resulted in different learning outcomes. For one group of students, research meant looking for "facts" to answer a series of discrete questions, and for another group of students, it meant uncritically gathering enough information to formulate a balanced position; for others, it meant critically assessing information sources, different values, and biases underlying different stances and perspectives represented. Similarly, Hayes and Nelson (1988) identified two distinct approaches used by students completing writing assignments across the campus in their study at an American, four-year research university. Based on their research, Hayes and Nelson characterized the approaches as "content-driven" versus "issue-driven," or "low-investment" versus "high-investment." These different understandings about the objectives of the writing assignments produced very different learning processes and products: "In the first case students would set out to reproduce information found in sources, and in the second they would transform source material to produce original syntheses or conclusions" (para 78).

The above two differing approaches towards research paper assignments of undergraduate students, identified by Hayes and Nelson (1988), are also recognized by other education researchers (Dobozy, 2011; Morton & Säljö, 1976a, 1976b; Roscoe & Chi, 2007; and Scardamalia & Bereiter, 2006) using different labels to characterize students' qualitatively different learning approaches to academic tasks. For example, Morton and Säljö (1976a, 1976b) used the terms "surface" and "deep" learning approaches, and Scardamalia and Bereiter (2006) used "knowledge telling" and "knowledge transforming."

Some researchers point out the pedagogical shift needed in educational institutions in order to properly facilitate students to be more productive learners. For example, Dobozy (2011) critically addresses the institutional barriers in schools that encourage students to rely on "teachers' knowledge telling approaches" (p. 36). The support for reflective knowledge building in education, rather than knowledge telling, has been addressed for some time as a critical issue for raising the new types of learners for the 21st century (Barr & Taggs 1995; Roscoe & Chi 2007; Scardamalia & Bereiter 2006).

Blended learning thus can be viewed as one of the methods to explore and develop the alternative learning environments in higher education to engage students in "knowledge transforming" and reflective knowledge building experiences.

From a Pilot Study to the Exploratory Study

Our experiences of the exploratory study will be presented as a case study in planning, designing, and delivering blended learning support around the first research paper assignment in the two different undergraduate foundational courses.

How the exploratory study came to be is somewhat complex. The study of blended learning support in the context of two undergraduate foundational courses was not what we originally planned. The collaboration of the subject librarian and the writing instructor started as a response to the call for a proposal for the 2011 Summer Session Innovation Fund from the University's Extended Education. The Innovation Fund was aimed at encouraging the developing of innovative blended learning projects to be delivered with 2011 summer courses. The initial idea was to do a pilot project in one well-established foundational course in the Faculty of Human Ecology that the subject librarian supported. The course we targeted was offered every year in the fall as a regular-semester course and additionally as a summer session course for many years. The opportunity to do a pilot project during the summer session made a lot of sense because it would provide a good learning ground for the experiment while the class size was small and easy to handle. The idea of supporting students in blended learning also had the potential for bringing the course instructor, the librarian, and the writing instructor into a common pedagogical planning space for designing the support for students around research paper assignments. It was also hoped that the pilot project would establish some basis for future collaboration in modifying and adjusting for the bigger, regular-semester class in the fall. We invited the Faculty to collaborate with the project. After receiving the grant and getting support from the Dean of the Faculty and respective Heads of the Library and the Academic Learning Centre, we proceeded with and completed the project.

The initial idea of doing the pilot project during the summer session in 2011 (from now on identified as "the summer 2011 course"), however, was quickly revised right after we had completed the project when we found out that the summer session had become the last run of the long-established course. A brand new foundational course was then scheduled to start in the following winter semester (January to April 2012; from now on identified as "the winter 2012 course") replacing the long-established course. Based on the success with the summer 2011 course project, we decided to proceed with another blended learning project. This time, however, the winter 2012 course had a set of different course circumstances: 1) the large class size of a regular-semester course, 2) different course content and topics, 3) a different set of research and writing assignments, and 4) a new course instructor with whom to collaborate. In order to continue with the experimentation, we received support from another internal grants program of the University, the Teaching & Learning with Technology Grants Program from the University Teaching Services.

The two blended learning projects thus together became an exploratory study instead of the pilot project we initially conceived. The study gave us an opportunity to explore ways to integrate blended learning support situated around research paper assignments in the context of two different foundational courses. These undergraduate courses were originally conceived for traditional, face-to-face, primarily lecture-based classroom environments in the same Faculty.

The Exploratory Study: Different Administrative Frameworks

The different administrative circumstances associated with the two courses in the exploratory study influenced the planning and delivering of blended learning support. Each course in the exploratory study was designated as a second year course that was required to complete a degree in the programs offered in the Faculty. The courses had the same value of "3 credit hours."[3] This meant a total of 36 hours was allocated for students to complete each course.[4] Although the credit value of the courses was the same, the summer 2011 course met twice a week for 7 weeks. On the other hand, the winter 2012 course met three times a week for 12 weeks. The summer 2011 course was small with a total of 11 students completing the course, while the winter 2012 course had a bigger class of approximately 130 students at the beginning of the semester and 114 students completing the course.

The different dynamics in the respective courses due to the class size may have influenced the way students experienced their learning in the course, and, in turn, their experience of the blended learning support. For the summer 2011 course, for example, the course instructor occasionally used the library's computer lab to have students work on the research paper assignments to provide a break from the otherwise, long hours of sitting in the same classroom during the days when they had a class. In the lab, the students discussed some of the issues they were encountering with research paper assignments by referring to the online course guide materials that were developed as a part of the blended learning support. This kind of in-class activity in the small class setting might have helped to make a better synergy between the face-to-face and online activities. The instructor for the winter 2012 course also referred to the online course guide as a useful reference when students asked questions about the assignment. In the winter 2012 course, however, even a minor discrepancy between the instruction given by the instructor in the class and what was included in the online course guide created some confusion among the students. We learned from the winter 2012 course that in a large class, careful coordination between class instructions and the instructions presented in the online guide becomes more important, especially when the librarian and the writing instructor are involved as collaborators in providing blended learning support. Furthermore, in a large class, flexible communications and facilitations to guide students become essential.

Another important difference between the two courses was the content covered. The two courses were designated as writing intensive courses in the Faculty involving two research paper assignments. Roughly half of the course grade was derived from the assignments. The remaining portion of the course grade in both courses was generated from two examinations covering the course content. For the summer 2011 course, the course content was the history and development of Human Ecology as the overarching area of study in the Faculty represented by a number of multidisciplinary programs. On the other hand, the winter 2012 course was a research methods course covering the main three clusters of research methods in social sciences.[5] Some students indicated in the online survey we conducted after the completion of the course that the subject matter of the winter 2012 course was rather dry and somewhat difficult to relate to, while we did not receive a similar response about the summer 2011 course from the students. In sum, the different nature of the course content in addition to different class size might have influenced how students experienced their learning in the course as a whole and in turn how they experienced the blended learning support.

The Planning and Developing of Blended Learning Support

There were some significant differences between the summer 2011 and winter 2012 courses in the planning, and in our attempt to incorporate blended learning support around their research paper assignments. The instructor for the summer 2011 course was teaching the same course for the second time after teaching the course in the previous fall semester. Since the course was a long-established foundational course in the Faculty, the subject librarian was very familiar with the course and its assignments. The writing instructor also had some familiarity with the course assignments, having supported the students from the same course over the years in her capacity as a writing instructor at the Academic Learning Centre of the University. Having the prior knowledge about the course assignments made a big difference during the planning discussions with the course instructor. A total of five meetings were held prior to the start of the summer 2011 course. We discussed the general idea of incorporating blended leaning components into the course to support and scaffold students as they worked on the various research and writing steps that were involved in research paper assignments. During these meetings, the task definition of the first assignment was substantially discussed, clarified and verified, together with the coordination of the course schedule, a review of course progression and key dates, and other administrative matters. The discussion was not always specifically related to the planning and designing of blended learning. For example, the instructor shared her passion for the use of "personal narratives" and "personal voice" in social sciences research. This angle was in fact very relevant to our thinking about guiding students along the research paper assignment of the course. This same point also resonated with the main purpose of designing blended learning support to connect students to the objectives of assignment. In the research paper assignment for the course, students were asked to elaborate on their orientation or relationship to Human Ecology as a broader disciplinary area represented by the Faculty using and incorporating academic and research sources. In addition, having the experiences of the students who took the same course in the past, especially having the sense of "disconnect" to the assignment among the students, made the subject librarian well prepared for the planning. The delivery of the blended learning in the summer 2011 course went very smoothly without any particular incidents.

The winter 2012 course, in contrast, was being offered for the first time, as a brand new course. Everyone, including the course instructor, was new to the course. We had to work with the new set of research paper assignments. In addition, for the subject librarian and the writing instructor, working on the winter 2012 course meant establishing a new working relationship with the new course instructor. Two preparatory meetings were held before the course started; these were followed by e-mail communications. In the planning meetings, the course coordination pertaining to the course coverage and its progression, key dates, and other administrative matters, became the priority for our discussions. We did not have the time for a thorough analysis of the task definition of the assignment as we had with the summer 2011 course. Furthermore, during the planning meetings, we had some difficulty in clearly situating or connecting the topic assigned in the first research paper assignment to its course content covered. We could not clarify its pedagogical purpose, but that would have been essential in developing some consensus among the collaborators to coordinate and guide students around research paper assignment.

In the winter 2012 course, the blended learning aspects of the course were in effect being segregated from the rest of the course instead of being integrated into the course during the planning stage with the course instructor. This was partly due to lack of time allocated for proper planning, but more importantly, due to the course syllabus, which focused on the course content rather than guiding or facilitating student learning or learning processes related to the assignments. Although the course was designated as a writing intensive course, research paper assignments were treated as separate activities from the rest of the course, according to its syllabus. This misalignment may be the real-life administrative constraint that binds many instructors who need to teach a large-size undergraduate course, and who often do not have adequate time to modify the syllabus and adjust classroom activities accordingly. Sessional course instructors, in particular, are often required to teach according to the syllabus that is provided to them. The winter 2012 course thus became fundamentally incompatible with the orientation of blended learning support as we originally envisioned, and we were rather restricted in our effort to incorporate blended learning support into the course already in its planning stage.

The Blended Learning Support and Its Delivery

In this section, how we structured the blended learning components in the summer 2011 and winter 2012 courses will be discussed.

Despite the different administrative frameworks associated with these courses, the basic structure of blended learning for both courses consisted of two basic components: 1) an online course guide that was developed using Springshare's Libguides platform[6]; and 2) an online interactive space that was established using the discussion board module on the University's Learning Management System (LMS). The objective of developing the online course guide was two fold: 1) to provide guiding instructions and materials to help students connect to the purpose of the writing assignments; and 2) to develop and gather all the useful resources in one online location that students could refer to when needed. For the summer 2011 course, for example, in addition to the instructional pieces related to the task and steps involved in each assignment, the online course guide included a library database search tool, the instruction on how to search relevant journal articles, writing tips, the resources for APA citation and formatting style, and links to course readings. Separate tabs in the online course guide's navigational bar organized the different resources covered and made it easy to browse the online course guide. The guide also contained a list of due dates for all the interactive exercises in the course, and it was seamlessly linked to the course site on the LMS. The course site's navigation bar easily linked back to the online course guide. Thus, students could go back and forth between the guide and the course site on the LMS seamlessly and easily. On the discussion board, students were given instruction at each stage to post their draft pieces and then to give feedback to two peers of their choice from the class or from their assigned group.[7] They were asked to provide feedback on peers' postings highlighting the effectiveness of the peers' pieces. For instance, was the piece a good example of an outline or an annotated bibliography according to the instruction provided? The discussion board was used with three pedagogical purposes in mind for students: 1) to have a wider audience than the instructor or the grader of the paper; 2) to experience the variation in writing styles or effectiveness in their peers' posts; and 3) to reflect on their own writing style or skills.

In addition to the online course guide and the online interactions on the discussion board, the subject librarian provided an in-class library session in each course demonstrating the use of a library tool to search and browse relevant sources according to research purpose of each assignment. For the summer 2011 course, since the class was small, half of the class time was allocated to a hands-on session. For the winter 2012 course, on the other hand, because of the large class, a question-and-answer period followed at the end of the librarian's demonstration. The specifics of the blended learning structures developed for the respective courses are provided as Table A and Table B in Appendix.

The Variation in the Blended Learning Support

There were some variations in how we structured blended learning support between the two courses. Since the summer 2011 course was small in size, the blended learning components kicked off with a simple, warm-up exercise of interviewing a peer in the classroom about his or her connection to Human Ecology. Students were then asked to write a paragraph introducing the peer and post it on the discussion board. The research paper for the summer 2011 course was, as earlier described, to write student's own definition of Human Ecology. In the winter 2012 course, on the other hand, the students were asked to study, reflect and write about their own perspective on "the determinants of health," which is a policy and research discourse that is relevant to all fields covered in the Faculty of Human Ecology. The students were specifically asked to do this by comparing and contrasting two differing approaches or examples of "the determinants of health" that they found and identified in the literature. The blended learning components for the winter 2012 thus started with a 4-day class-wide brainstorming session using Twitter after a brief instructional session by the subject librarian on how to conduct the Twitter session. The students were asked to type and share their own personal meanings of "health" up to 140 characters at a time, at least twice during the 4-day period. The streaming of the Twitter feeds was posted on the online course guide to be monitored by everyone. This brainstorming exercise was designed to given students a warm-up leading to the main topic of the research paper assignment.

For the research paper assignment in the winter 2012 course, the students were asked to study, reflect and write about their own perspective on "the determinants of health," which is a policy and research discourse that is relevant to all fields covered in the Faculty of Human Ecology. The students were specifically asked to do this by comparing and contrasting two differing approaches or examples of "the determinants of health" that they found and identified in the literature.

Another important variation in the winter 2012 course was the incorporation of the Online Writing Tutor, a free service available from the Academic Learning Centre on a voluntary basis to all students at the University. The students were asked to submit a draft thesis statement with an outline to the Tutor, and received quick feedback within 24 hours. The writing instructor provided in-class instruction on thesis statements and explained how to use the Online Writing Tutor for the assignment. There was also a minor variation in how we used discussion board posting in the winter 2012 course. In the summer 2011 course, the students shared their research and writing processes by mainly posting their draft pieces for their peers' feedback. For the winter 2012 course, the students were also asked to post the final version of the introductory section of the paper for the peers' feedback as their final step in the assignment. The objective was to re-enforce their understanding of the role of the introductory section in research papers.

The Alignment and Misalignment of Blended Learning Support

Aligning the face-to-face classroom and online activities with the broader learning objectives of the course, more specifically with the purpose of research paper assignment, should be the core activity for developing blended learning support and the focus of the collaboration (Biggs, 1996; Biggs & Tang, 2011; Garrison & Vaughan, 2008). In the exploratory study, however, the librarian and the writing instructor initially had only a vague understanding of how to implement alignment. The original idea of how to structure blended learning support in the course, instead, was mainly drawn from the knowledge of the long-established foundational course in the Faculty as a prototype. The summer 2011 course definitely had an advantage of developing blended learning around its assignment. The original assignment already had sequentially broken-down research and writing activities into mind mapping, outlining, and creating an annotated bibliography, and submitting a draft and final paper. This gave us a prototype of sorts to guide students, first with the purpose of the research paper assignment, then with the sequentially broken-down steps of research and writing processes. For the summer 2011 course, we spent some time working on the paper assignment itself by clarifying its objectives and purpose in order to include some useful guidance in the online guide. In addition, we included the video clips of three recent graduates from the Faculty whom we interviewed as additional materials to help students connect to the assignment at more personal level. In the video clips, the recent graduates talked about the work they do in their respective fields highlighting some personal accounts of their connection to Human Ecology. Preparation for the rest of the blended learning support for the assignment involved developing specific instructions to guide online activities on the discussion board and related tips and resources in the online course guide. For the summer 2011 course, we did not experience any misalignment issues during the delivery of the blended learning support.

For the winter 2012 course, on the other hand, since we did not have enough time to discuss the assignment in detail during the planning meetings, we relied, to a large extent, on the explicit information provided in the assignment sheet to develop blended learning components. For this reason, important questions, such as what is the purpose of the assignment, what exactly students are supposed to "compare and contrast" about "the determinants of health" as described in the assignment sheet, for example, remained somewhat vague. As we previously discussed about the planning for the winter 2012 course, there was not much room to integrate blended learning aspects properly into the course. We simply rewrote the original description of the assignment provided in the assignment sheet by breaking it down into easier steps and provided them as a guide for the assignment in the online course guide. We also included links to a number of different references to "the determinants of health" from government, intergovernmental and academic sources on the Internet. We could not, however, develop additional materials or opportunities to connect students to the purpose of the assignment.

Similarly, specific online activities we provided in the winter 2012 were developed somewhat separately, with inadequate time for planning properly to align or coordinate with the course instructor. This inadvertently led to some confusion among the students. For example, when students were asked to post a draft paragraph of their initial understanding of "the determinants of health" on the discussion board, as a subsequent step after the brainstorming session, many students were confused as to what were expected in the paragraph. Some students ended up repeating what they produced during the brainstorming session. Although no guidance was in place after the brainstorming session due to lack of coordination to bridge these separate activities, the students ideally could have been guided through the form of class discussion in reference to their research readings to help them orient with "the determinants of health." Questions such as "Why 'the determinants of health' was used in the course assignment?" or "What is the overarching role or relevancy of such a policy and research discourse in their fields?" might have been helpful for students as an introduction to "the determinants of health."

Another major confusion in class occurred when the subject librarian conducted a library session for the class. She demonstrated how to use keywords to formulate search strategies in order to effectively search and browse potential sources using a library database tool. Since the main coverage of the winter 2012 course was three key clusters of research methods in social sciences, she demonstrated ways to search and browse the tool using "determinants of health" as the key search term, combining with another term associated with a research method of choice, and any additional term representing a topic of choice.

It turned out, however, that the course instructor wanted students to approach "the determinants of health" at a general conceptual level and addressing research methods was not the focus of the assignment. After the confusion occurred due to the subject librarian's different interpretation of the assignment, the course instructor used separate class time to clarify what were specifically expected in the assignment using her PowerPoint slides. The subject librarian followed up by setting up a search feed of the articles related to the policy and research discourse in the online course guide to ease the confusion.

When we reviewed the planning and delivery of the blended learning support in the winter 2012 course, we found that the support should have been aligned more closely to how the course instructor was going to introduce and discuss the assignment and facilitate students in the class. The two effects of the misalignment described for the winter 2012 course, in turn, highlighted the gap between the original intention of designing blended learning support and the pedagogical orientation embedded in the course syllabus and its associated teaching practice. There is no doubt that we required substantial time to negotiate the gap and to ensure that there was thorough coordination among the collaborators in order to guide students. Garrison and Vaughan (2007) emphasize "reconceptualize[ing] and redesign[ing] the entire course" (p. 106) as an important first step for planning blended learning that is not simply "a juxtaposition of new technology and old pedagogy" (Levey, 2006, as cited in Garrison & Vaughan, 2007, p. 7). This essentially requires a higher-level commitment, probably at the Faculty level, to providing more student-centered learning environments to support undergraduate research and writing skills development. Unfortunately, this was beyond the scope of the exploratory study we embarked on.

Student Learning Experiences in the Exploratory Study

We were interested in the way students experienced blended learning support in the exploratory study. We conducted to this end: 1) a class survey targeting the entire class population at the end of the respective courses, 2) semi-structured interviews recruiting the student volunteers at the end of each course, and 3) two focus groups[8] with a total of 7 students who had taken the same course as the summer 2011 course during the previous 4 years.

For the summer 2011 course, the paper-and-pencil survey was conducted in the class on the last day of the course. For the winter 2012 course, a web link to an online survey was made available for the students to participate for the duration of a week after the completion of the course. We recruited 7 and 14 student volunteers to participate in the interviews for the summer 2011 course and the winter 2012 course, respectively.[9] All students we interviewed for the summer 2011 course were in their 2nd year of their undergraduate program; on the other hand, we interviewed a mixed group of students for the winter 2012 course: four 4th year students, five 2nd year students, and five 3rd year students in their respective program in the Faculty. The objective of the focus groups was to make a general comparison, if any, of the learning experiences of the students in the summer 2011 course with those students who had taken the same course without blended learning support.[10] For the summer 2011 course, the experiences of locating relevant research sources for the assignment by the students were drawn both from the survey results, the annotated bibliographies posted on the discussion board, and some observations made during the library session; there was no equivalent set of data to draw from for the winter 2012 course.

Table 1. Methods used to gather student learning experiences

Course	Class Survey		Interviews	Focus Groups
	No. of Students	% of Response		
Summer 2011	11	100%	7 Students*	7 Students
Winter 2012	42	36.9%	14 Students**	N/A

*All 2nd year students. **Five 2nd year students, five 3rd year students, and four 4th year students.

Table 2. Results of a survey question: how do you rate your overall learning experience in the course on the scale of 1 to 5?

Rating Course	1	2	3	4	5
Summer 2011	0	0	1 (9.1%)	2 (18.2%)	8 (72.7%)
Winter 2012	3 (7.69%)	7 (17.95%)	12 (30.77%)	14 (35.9%)	3 (7.69%)

(The number of students who rate a scale of 1 to 5 with a corresponding percentage of the respondents in the parentheses)

Overall Learning Experiences of the Courses

In this section, we will first summarize the survey results of how students evaluated their learning experiences in each course. Then, we will describe how students experienced blended learning support in the respective courses drawing from the survey and interview results, focusing on their experiences with the online course guide and the discussion board activities. In addition, students' experiences of locating relevant sources for the assignment in the summer 2011 course, and their experiences of the Online Writing Tutor in the winter 2012 course will be discussed. A summary of the research methods used to explore how students experienced respective blended learning supports is shown in Table I.

The surveys designed for the summer 2011 course and for the winter 2012 course reflected corresponding blended learning support designed and delivered; as a result, they were not identical. However, both surveys shared one common question, which asked students to rate their overall learning experience of the course on a scale of 1 to 5. The comparison of the responses to the question thus indirectly indicated the general different class dynamics that existed in the two courses. The different class dynamics were possibly due to the difference in the class size or the different course content as they were previously discussed. For the summer 2011 course, all 11 students who completed the course (100%) participated in the survey and the majority rated either 4 or 5 as their overall learning experience of the course. Specifically, eight students rated 5 (72.7%), two students rated 4 (18.2%) and the remaining one student rated 3 (9.1%). For the winter 2012 course, of the 114 students completed the course, 42 (36.8%) students responded to the survey. The responses to the same question spread much more widely for the winter 2012 course: 3 (7.14%) respondents rated 5, and the rest of the respondents, 14 (33.34%), 12 (28.57%), 7 (16.67%), 3 (7.14%) rated 4, 3, 2, and 1, respectively, with 3 (7.14%) not responding to the question. Table II summarizes the results.

The Online Course Guide

In general, many students from both courses found it very useful to have all the reference and instructional materials in one place on the online course guide, and indicated that the guide assisted them working on the assignments. Many students referred back and forth to the online course guide in order to orient themselves to the assignment; as one student from the summer 2011 course indicated, "Whenever I was confused, I would go there." Although there were no additional instructions or materials given for the assignment in the online course guide for the winter 2012 course, some students still appreciated having the guide to the assignment as we had provided in the online guide. The online survey results from the winter 2012 course indicated that the APA resources tab was the most frequently used and ranked as the most useful resource in the online course guide. (See Table A and Table B in Appendix for the resources provided for respective courses). The students also found the instructions about thesis statements, and other writing tips in the online course guide to be useful. There were a few students who were not particularly keen to use the online resources for both courses; one student in the summer 2011 course, for example, indicated that she preferred to use a handbook instead.

The Students from the Summer 2011

The majority of the students from the summer 2011 course had positive learning experiences with the blended learning support designed around the research paper assignment. Some students also strongly expressed, both in their interviews and survey, their appreciation of the course content—the history of Human Ecology—and of the research paper as a vehicle for expressing their personal voices. One student realized that the research and writing processes are "not just putting in random filler." Another student learned to connect ideas: "Before I didn't connect ideas … I just stated them and went on to the next point." In comparison to the learning experiences of the students who participated in the focus groups, the students in the summer 2011 course seemed to have gained more positive learning experiences. The students in the summer 2011 course clearly appreciated learning the significance of the APA style and its role and function in the research and academic writing in their fields.[11] One student, for example, emphasized the importance of keeping her own voice while working in the APA style. This was a sharp contrast to the strongly expressed dissatisfaction by half of the focus group participants, who had previously taken the same course without blended learning support. They found that they were overly penalized by losing marks on some technical APA style details, and that the intellectual benefits of the assignments in the course were rather low. The students who took the course previously had also dealt with the same steps involved in working on the assignment, such as mind mapping and outlining, but submitted each draft piece they had worked on at every stage of their writing processes; and each piece was individually graded towards their marks. The reason for the dissatisfaction expressed in the focus groups is largely a matter for speculation. Some students may have inadvertently viewed or experienced the research and writing steps including APA formatting and style rules as somewhat separate, segregated activities, rather than experiencing these steps as comprising the various negotiating processes for completing the paper. For the summer 2011 course, in order to incorporate blended learning support, all the writing steps designed in the assignment were converted into participatory marks from the original graded marks. This was perhaps more successful in presenting the idea to the students that these sequential steps are important research and writing processes.

The use of the discussion board module of the LMS in sharing and giving feedback among the students created an alternative learning environment to the class lectures. One student appreciated the arrangement: "Anything that takes you away from lectures and note-taking." This structure probably also contributed to giving students the sense of connections between the sequential tasks involved in completing their papers. The interactions on the discussion board at various stages of research and writing processes indeed had some positive effects on their learning. Five students out of the eleven students we interviewed for the summer 2011 course specifically expressed how sharing their draft pieces, giving feedback, getting feedback, or reading the feedback given to others, had some positive effects on them. The following comments highlight specific effects experienced by the students:

- "Reading other people's bib's helped a lot because other people find better sources than you."
- "You never ever get to look at other people's material … you see how other people learn and write … you saw this online." The same student also pointed out the act of commenting on their peers' strengths itself had positive effect on her.
- One student shared that her peers' outlines were written in the reverse order of hers. In addition, she saw the value in the detailed approach of others: "For the future, my outline will be a lot more detailed."
- Reading the peers' comments and questions gave one student reminders and good ideas: "You started formulating your own ways."
- Receiving positive feedback from one's peers gave another student confidence: "You seldom hear feedback from other people."

Although one student indicated that she did not experience any significant learning effects from the interactions on the discussion board per se, she articulated the importance of sharing her own drafts with the peers. For her, the confidence in her own writing increased and it brought home to her that there was a broader audience than just "the prof." One student, however, was dismissive of online discussion activities: "No one actually read [the posts] … they just did it for the marks."

Identifying and Browsing Relevant Sources for Assignment

The benefit of clearly understanding the purpose of the assignment among the students in the summer 2011 course was evident when the subject librarian conducted a library session. It offered a database search demonstration followed by a hands-on session in the computer lab in the library. During the hands-on session, the students searched individually, without any difficulty, using some of the database searching and browsing methods the librarian demonstrated. Based on the annotated bibliographies the students posted on the discussion board, they showed amazingly diverse collections utilizing a variety of sources, thereby reflecting different, unique perspectives the students were working on. In the survey, the students were asked to rate their success in finding relevant sources in terms of what they accomplished in the paper. Five and six students (45.5% and 54.5%) rated either 4 or 5 out of a scale of 1 to 5, respectively. Five students left some comments in the open comment section of the survey question and indicated that they appreciated the usefulness of the library search tool in locating research and academic sources. One student, however, did not learn anything new from the library session.

The Students from the Winter 2012 Course

Despite the confusion associated with the misalignment of the face-to-face and online activities in the winter 2012 course, the blended learning support offered some diverse learning experiences among the students. In some respect, having the confusion regarding the assignment at the beginning might have created a space for students to engage in some problem solving to clarify the task demands of the assignment.

According to the student interviews, potential negative influences from the misalignment were minimal. Of the 14 students we interviewed, 2 students specifically indicated that having two sources of information about the assignment at the beginning brought some confusion regarding what was actually being expected in the assignment. In the end, however, the interactions with the Online Writing Tutor helped them resolve the confusion and brought them back to be "on the right track" with the assignment. In spite of the initial confusion, the same two students seemed to have gained some positive learning experiences. Both students highlighted in their interviews the importance of doing an outline for the paper properly as a means to bring about and develop a sense of control and self-regulation in their writing activities. One student commented that it was associated with having "a better control of time." The other student indicated her appreciation of the Tutor's feedback to her outline by elaborating that outlining meant "being responsible for my own work" and "always going through what I'm writing to see what I'm doing … do a self-check." She further extended her comment by indicating that having a sense of ownership in her writing is important and this was what she learned in the course.

The Online Writing Tutor support in the winter 2012 course definitely played an important role in salvaging and mitigating the confusion among the students that had arisen from the misalignment aspects of the blended learning support. Eight students strongly indicated that the feedback they received from the Tutor had positive effects on their work on the assignment. Four of those students were redirected to the original assignment sheet after being pointed out by the Tutor that their drafts were "not on the right track." One student, for example, exclaimed, "I could've failed if I didn't have that feedback." Five students we interviewed indicated that they benefitted from a specific suggestion given by the Tutor. One student, for example, received a useful suggestion for setting up her "compare and contrast" in the paper. She referred to the suggestion "quite a few times" as she worked out on the paper. Two other students were directed to revise their thesis statements and outlines. The Tutor pointed out that theirs were too broad and general and needed to be narrowed down. Another student realized the importance of aligning his thesis statement to the body of the paper: "The paragraphs are really involved in [*sic*] the next paragraphs." Two 4th year students who did not appreciate the online activities offered in the course contacted the writing tutor on their own after they received the feedback from the Online Writing Tutor; one contacting the tutor on the phone, the other meeting in a face-to-face session to clarify the "why?" and "how?" of thesis statements and the organization of the paper for the assignment.

The interactions on the discussion board influenced students' learning in a variety of degrees. Ten out of the fourteen students we interviewed from the winter 2012 course expressed some positive effects on their learning. For example, four students tried harder and edited carefully before posting their pieces because they had to share their draft pieces on the discussion board. One student said: "With this experience, I was more challenged to express myself really well. Peer influence impacted greatly because you feel that these are my peers and I've got to show them what I know. And so it impacted my work." Another student indicated: "You want to present yourself in the best way possible." In her case, her extra efforts rewarded her by getting more attention from the members of her group on the pieces she posted. Some students appreciated the asynchronicity of the discussion board. It allowed them to work at home or it gave them a comfortable zone to interact. For example, one student stated: "It by-passed that awkwardness. It's a bit more comfortable."

For some students, viewing the peers' postings provided them with some other learning opportunities. For example, it helped students to situate their writing skills among the peers as one student said: "You could tell who didn't necessarily care. … I've been in that boat where I have no clue. … It gives you a sense of where you're sitting in the class." It also gave some students the opportunity to identify different approaches made or different angles taken by their peers for the same assignment: "Reading what other people wrote was really nice because people approached it in a different way than I would have." For another student, viewing the variation in her peers' approach helped in her meaning-making and in setting a direction to her paper; she further related her learning experience of blended learning support by referring to how she came to be more "independent" as an undergraduate student during her third year when she began taking more responsibility in her schoolwork. Viewing the posting of their peers allowed some students to also identify a good example or model. One student, for example, recognized a good writing style used among her peers and identified it to be "simple, and basic and to the point"; this allowed her to simplify her draft by taking out some "thesaurus words."

Two 4th year students did not find any usefulness in the online interactions. One of them indicated that because she is not accustomed to use an outline in her paper, "it felt like an extra step." Both of them, however, thought that more of the conversational discussions in the class rather than online activities would have worked better for them. They referred to how they appreciated the group discussion in class led by the writing instructor for the 2nd paper assignment.

During the interviews, some students reflected on their development and growth as academic writers. The interviews with the students definitely reminded us of the diversity in where students are with their learning needs and readiness about academic writing. Two students reflected on the various research papers that they had written in their undergraduate career so far and concluded that having more practice would be vital if they were to improve their own research and writing skills. Two other students indicated that the blended learning aspects of the course greatly influenced them in reflecting on their writing styles that they carried forward from their high school years. One student from this group shared how well he did and received a good mark on the assignment. He shared how successfully he negotiated through the feedback he received from the Online Writing Tutor and his peers on the discussion board, and by clarifying the assignment objective with the course instructor. He then pondered his readiness to adopt a more "mature," university style English that he observed among his peers on the discussion board. At the end of the reflection, he reasoned that his high school style would not work at some point as the audience was expanding for him. In addition, one international student shared how she was growing as a foreign student since she first arrived at the University of Manitoba three years ago and how she came to feel more comfortable studying in the "Canadian" environment. For her, her English grammar was her primary concern. During her interview, she expressed a need for more examples, for models of good papers, and for her grammar to be corrected by the writing tutor.

In conclusion, despite the misalignments of the blended learning support, students actively looked for cues or clues to understand what was being asked in the assignment by monitoring whether they were on "the right track" with assignment at various stages. The feedback the students received from the Online Writing Tutor—in some cases, more directly from the tutor—and through the interactions on the discussion board, gave them some tangible cues or clues to go back to their draft and work it through. In fact, four students in the interviews suggested having "an open forum for problem-solving and discussion" beyond the interactions that were already included in the blended learning support. One student alluded to the missing aspect of the blended learning support by pointing out that she needed more help during the class in clarifying what was being specifically asked to compare and contrast in the assignment. The same student also wished that the Writing Tutor's feedback was more descriptive and detailed. Her comments seem to resonate with the lack of a clearer purpose of the assignment with which we struggled during the planning and developing of the blended learning support.

The Key Potential of Blended Learning Support

Blended learning support, if it is properly integrated into courses, has the potential to develop learning environments that are more conducive to engaging students in the complex processes of completing research paper assignments. Blended learning support has the potential, more specifically, to create learning spaces to allow students to "make sense" of the complex processes by reflecting on their own learning, and to guide their own learning as they work on assignments. In the student interviews, some students clearly indicated or implied that they were learning to self-regulate and work through academic writing processes. In both courses—although time management was not specifically highlighted as a theme among the student learning experiences—some students shared their increasing awareness of time management when they work on research paper assignments. Time management is often taught in the first year university orientation course as an aspect of student academic life. It seems that the blended learning support helped some students to be aware of time management as a means to gain a sense of control over their work especially after realizing that more time is needed for working through the multiple steps involved in research paper assignment.

Blended learning support was successfully integrated into the summer 2011 course and made the assignment's purpose and its connection to the course content more visible to the students. The overall positive learning experiences with the course as a whole came through both during the student interviews and from the survey results. Success of the summer 2011 course is largely due to the fact that all the collaborators, including the course instructor, were quite familiar with the course and its assignments prior to the project. We also allocated more time for having open discussions around the course and the assignment during the planning stage. Another important factor for success was that the original course syllabus already included the feature for facilitating writing processes; this made the conversion to blended learning support easier. It was, however, the experiences from the winter 2012 course—where we encountered the problems during the planning and delivery phases—that encouraged us to look for a guiding framework and some designing principles for blended learning support. Having such a framework and guiding principles would be beneficial for the collaboration among course instructors and support professionals to align and coordinate online and face-to-face elements of a course.

A Guiding Framework for Blended Learning Support

Butler and Cartier (2004) provide a useful guiding framework for thinking through the designing of learning environments that facilitate student engagement in any academic work. Central to their framework is students' self-regulatory activities—that is, how students monitor their own thinking processes and guide or regulate their own activities to achieve the objectives of academic work in a given learning context and environment. Butler and Cartier provide five interacting phases of student engagement to cultivate students' self-regulatory activities in any academic tasks including undergraduate research paper assignments:

- **Task Interpretation:** To carefully decipher the requirements of the research paper assignment.
- **Planning:** Setting objectives and selecting approaches for managing the writing task.

- **Enacting:** Implementing selected strategies.
- **Monitoring:** Keeping track of progress in relation to objectives.
- **Evaluating:** Generating feedback for oneself on how thing went.

Butler and Cartier's (2004) framework of student engagement situates students' task interpretation of academic work as the key learning activity: It "sets [their] learning in motion and establishes directions for learning" (p. 1743). In the framework, students' task interpretation is viewed as "a joint function of students' metacognitive knowledge about tasks, their conceptions about the nature of academic work, and how well students actively and strategically focus attention on deciphering task demands" (p. 1743). Butler and Cartier's framework places the task analysis of a given academic work in the broader preparatory analysis required for developing blended learning support. This helps to avoid the pitfall of losing focus of what the instructor wants students to learn in the process. Defining and understanding the requirements for the assignment and what the instructor wants students to learn in the assignment are essential aspects of planning and developing blended learning support. Research shows, however, that a tightly defined or detailed guideline to the point of providing a template for research paper would be counterproductive. In this situation, students often end up producing acceptable papers with minimal time and effort taking shortcuts without engaging in the kind of thinking processes or negotiations required in producing "deeper" learning outcomes (Nelson, 1990). The implication of applying the Butler and Cartier's framework for designing blended learning support therefore is to intentionally guide students' learning processes and self-regulatory activities with explicit instructions.

Butler and Cartier (2004) further identify three interrelated areas for students to understand and manage their own learning when they are working with complex academic tasks. Some examples of how students responded to the cues and clues generated by the blended learning support in the winter 2012 course partially correspond to the three areas identified by Butler and Cartier. Identification of these three areas is useful for guiding blended learning designers and developers to think through the interrelated elements they have to work on. The first area is *task purpose*, which refers to students' understanding or interpretation of the goal or the purpose of the assignment. (Here, the research paper assignments.) The second area is *task structure*. Referring to our example of research paper assignments, students need to have a grasp of the basic structure of research papers they were asked to produce. The third area is *task components*. Butler and Cartier use the knowledge of good writing as an example for task components by referring to "four interlocking and recursive stages, namely planning, drafting, editing and revising" (p. 1739).

Biggs (1996) and Biggs and Tang (2011) advanced "constructive alignment" as an important designing principle for a course and as a means to ensure quality learning in higher education. Butler and Cartier (2004) similarly recommend that various design elements of learning environments have to be thought through by aligning the connections between the activities, task components presented, the instructions provided, and how tasks or the final products are graded. Some key guiding questions and points provided by Butler and Cartier for designing learning environments are also useful for designing blended learning support around research paper assignments:

- Clarify the goals for students' learning. What do you hope they get out of the research paper assignment?
- What do students need to do to accomplish the goals?
- What tasks are to be chosen for guiding students?

- Do the tasks selected contribute to students' understanding about the nature of the academic work?
- Do the tasks selected actually foster intended learning outcomes? "How do learners have to think? What do they have to know? How do they have to perform?" (Jonassen et al, 1999, p. ix, as cited in Butler & Cartier, 2004).
- Provide explicit instructions to promote students' self-regulating activities.
- Promote students' active reflection on processes for completing the research paper.
- Coordinate evaluation or assessment to match task purposes.
- Promote students' self-evaluation.

Blended learning support definitely has the potential for enhancing the "quality of learning" (Biggs, 1996; Biggs & Tang, 2011). The blended learning model can improve students' learning environments by aligning situational factors that the course instructor or course designer has control over. According to Nelson (1990), students draw from two categories of resources to interpret their writing assignments: 1) individual or personal variables; and 2) situational or context-specific variables. The individual or personal variables include students' past experiences with writing assignments or the subject matter addressed in the course, and their familiar strategies to deal with similar assignments. On the other hand, the situational or context-specific variables refer to the learning environments of the course. Specifically, Nelson lists "the criteria used to evaluate products, the quality and frequency of feedback, and the nature of the instructions and other explicit support materials students receive for completing assignment" (p. 391). Nelson found in her research that "students actively interpret the assignments they receive, and that students often rely on implicit cues to determine what counts in completing tasks" (p. 391) as the chapter's case study noticed, in particular with the winter 2012 course.

The Barrier to Implementing Blended Learning Support

Integrating blended learning support by successfully aligning online and in-class activities is a challenge for existing traditional undergraduate foundational courses, especially if the research paper assignment's relationship to the course content is not inherently obvious as presented in the syllabus. The challenge is perhaps inherent in the fundamental gap between the assumption of blended learning support, and the assumption of the traditional face-to-face, lecture based classroom-teaching practices. The former focuses on student learning and learning processes while the latter focuses on the course content and the end product. This pedagogical difference was discussed in Barr and Tagg's (1995) influential article *"From teaching to learning: A new paradigm for undergraduate education."* In the article, they advanced the general pedagogical shift in higher education to "*Learning Paradigm*" from its traditional practice of "*Instructional Paradigm*." With the "*Learning Paradigm*," they envision the purpose of higher education to be "create[ing] environments and experiences that bring students to discover and construct knowledge for themselves" and "to make students members of communities of learners that make discoveries and solve problems" (p. 15). The teaching practice associated with the traditional "*Instructional Paradigm*" emphasizes teaching course content, but is not exactly geared towards student learning, learning processes and discoveries. This paradigm thus is the major barrier to the implementation of the blended learning support we originally envisioned in the exploratory study.

FUTURE RESEARCH DIRECTIONS

In our exploratory study, we were basically on our own to work on the blended learning support projects except when we consulted on and off with the LMS manager to get his technical support. It would have been very helpful if there had been a community of practice on campus to go to and get some feedback, or just to share what we were doing or hearing about the other similar projects on campus. How might we create the campus environment or culture or a community of practice through which new ways of teaching and learning are shared or encouraged to further explore? How might higher education institutions leverage faculty initiatives or grassroots collaborations to manage the changing landscape of teaching and learning practices? These are among the many questions related to developing and shaping the right institutional environment and culture for supporting more student-centered learning environments.

The March 2013 issue of *the Internet and Higher Education* devotes its entire issue to different perspectives addressing the blended learning policy and implementation. For example, Garrison and Vaughan (2013) document two instances of blended learning initiatives, which were developed by using the Practical Inquiry model and the Community of Inquiry framework,[12] respectively, at two different Canadian higher education institutions. They conclude that committed collaborative leadership that can offer "a clear vision, specific action plans, teaching recognition, and the resources to make this happen" (p. 26) is essential to make significant change in teaching and learning practices on campus. Bohel Carbonell, Dailey-Herbert, and Gijselaers (2013), on the other hand, document the bottom-up approach used at a midsized European university. At their university, problem-based learning (PBL) curricula already constitute the cornerstone of the teaching and learning practices. Their project was to incorporate blended learning into their courses in three years. The already-established PBL curricula certainly gave their university an advantage for incorporating blended learning in terms of their readiness for student-centered teaching and learning practices. They still state, however, that a common vision and "high levels of commitment from administrators and faculty" (p. 33) had to be in place in order to successfully incorporate blended learning into their PBL curricula. The case study showed that the bottom-up approach was essential in making a difference in their learning environments by mobilizing the faculty's own initiatives, planning, and development on the ground. The bottom-up approach thus had to be supported in the context of having a common vision with the institutional commitment at their university.

With the increased affordances of Information and Communication Technology, and as more wireless devices are being integrated into our lives and society at large, it increasingly becomes crucial for higher education institutions to manage change by leveraging the affordances created for shaping student-centered teaching and learning practices. Within this context of change, potent areas of research include: new ways of organizing or conceptualizing courses or programs to broaden the learning opportunity for an increasingly diverse student body; original ways of evaluation and assessment; creative uses of interactive and social networking tools to facilitate student learning; and innovative ways of collaborating across different administrative units on campus to effectively incorporate the potential of blended learning.

CONCLUSION

This chapter presented an exploratory study of designing and delivering blended learning support around research paper assignments in the context of two different undergraduate foundational courses that were offered in the Faculty of Human Ecology at the University of Manitoba in Canada. Blended learning support has potential in creating better learning environments to engage students in guiding their own learning as they work on research paper assignments. In addition to what was learned in the exploratory study, working guidelines for designing and developing blended learning support were offered in the chapter, drawing mainly from Butler and Cartier's research (2004). A shared vision and corresponding institutional support, which are initiated and backed at the leadership level in higher education, are critical in order to ensure proper planning and development of blended learning support as part of the undergraduate curriculum development.

ACKNOWLEDGEMENT

The author would like to acknowledge Ms. Kathy Block, the writing instructor, whose collaboration was indispensable in carrying on and completing the exploratory study. Numerous conversations she had with Ms. Block before, during and after the respective blended learning projects were essential in shaping the direction of the exploratory study. The author would like to specially thank Ms. Lenora Wiebe and Mr. Walter Roberson for generously going through the entire chapter at its draft stage and providing valuable editorial feedback. She also would like to acknowledge Dr. Monique Dumontent and Ms. Block for their valuable editorial feedback.

KEY TERMS AND DEFINITIONS

Constructive Alignment: An important principle for designing teaching and learning activities and it was advanced by Professor John B. Biggs. The principle utilizes a constructivist understanding of how learning takes place and encourages the designers of learning environments to align the learning activities to the intended learning outcomes.

ENDNOTES

1 Garrison and Kanuka (2004) write, "Blended learning is both simple and complex" (p. 96). The quote referred to as its definition is their simple definition of blended learning. They acknowledge that implementing blended learning is enormously complex in its implementation: "the challenge of virtually limitless design possibilities and applicability to so many contexts" (p. 96).

2 At the University of Manitoba, where this exploratory study took place, its Library Administration manages all library units across two campuses in addition to all the hospital libraries in Winnipeg, the city where the University resides. The Academic Learning Centre, on the other hand, is administered under Student Affairs, a separate umbrella administrative unit of the University. In comparison, at the University of Washington, Bothell, a number of academic support units including the campus library, the Writing Center and information systems are under one administrative unit, Academic Services (Leadley & Rosenberg, 2006).

3 This means 3 class hours are being covered each week during a fall or winter regular semester.

4 During the regular terms, the foundational course traditionally included a weekly lab time with a teaching assistant to go over technical aspects of preparing research papers. During the summer sessions, the instructor incorporated the additional lab hours into the class time. In the exploratory study, blended learning replaced those additional lab hours.

5 The course covered qualitative, quantitative, and mixed methods in social sciences research.

6 Many academic libraries adopted Springshare's Libguides platform to manage library subject guides to support their constituencies. The Libraries at the University of Manitoba began subscribing to the Libguides in the early 2011 and subsequently officially introduced their subject guides on the Libguides platform in September 2011. The platform was a better option at the time than developing the entire blended learn-

ing support on the University's Learning Management System, in terms of its ease of use for developing and managing the online course guides.

7 During the summer 2011 course, the class was small and shared the same discussion board, while during the winter 2012 course students were assigned into 8 different groups.

8 Those 7 students who were recruited for the focus groups took the same course during the four different course offerings: fall 2007, summer 2009, fall 2009, and fall 2010. There were three different instructors involved in teaching these courses. Half of the students who participated in the focus groups expressed some negative experience of the course assignments that mainly focused on technical matters such as the APA style and the topic of plagiarism. They indicated that they were rather "nitpicked" about the details of the APA style and evaluated the intellectual expectation of the research paper assignments to be rather low. During the focus group meeting, they still expressed some frustration they experienced with the marks deducted for some formatting or punctuation matters related to the APA style.

9 All the research instruments and procedures used for the exploratory study were reviewed and approved by the Research Ethic Board, Fort Garry Campus, University of Manitoba, prior to conducting the survey and interviews for the respective blended learning projects. The first 45-minute focus group took place with 5 students in May 2011 and another one with 2 students in September 2011. We conducted interview sessions with the students from the summer 2011 course during the summer months and September in 2011. We conducted the interview sessions with the students from the winter 2012 course during the months of April and May 2012.

10 The students in the focus groups had extra lab hours if they took the course during a fall term; or additional class time if they took the course in a summer session. Refer to #4 note.

11 It is also important to document here that in the summer 2011 course, the instructor discussed and guided students in the class about the APA citation and formatting style.

12 Refer to Garrison, Anderson, and Archer for both the Practical Inquiry model (2001) and the Community of Inquiry framework (2000).

This work was previously published in Practical Applications and Experiences in K-20 Blended Learning Environments edited by Lydia Kyei-Blankson and Esther Ntuli, pages 341-368, copyright year 2014 by Information Science Reference (an imprint of IGI Global).

APPENDIX 1

Table 1. The blended learning support structure for summer 2011 course

Assignment	"In this paper, you will research the definition of Human Ecology and develop a personal, reflective definition. You will discuss your personal definition as it relates to definitions of others and use academic sources to draft your paper." (From the Assignment Sheet of the summer 2011 course.)
Course Context	This foundational course covers the history of Human Ecology and teaches research & writing skills.
Online Interactions	• **Interviewing a Peer:** Students interviewed a peer in class about his or her connection to the chosen field in the Faculty of Human Ecology, such as why s/he is pursuing a program in the Faculty or what might be his/her career aspiration. • **Developing a Paragraph:** Students developed a paragraph summarizing the peer's connection to Human Ecology and posted on the discussion board. • **Developing a Draft Outline:** Students developed a draft outline of their paper using an online mind mapping/ outlining tool and posted on the discussion board. • **Reviewing Postings by Peers:** Students reviewed the draft outlines by peers and responded to two postings that they found effective as outlines. • **In-class Library Session**: The librarian demonstrated how to search a library database tool for browsing and identifying relevant sources for the paper, followed by a hands-on session. • **Developing a Draft Annotated Bibliography:** Students developed a draft, annotated bibliography for the paper and posted on the discussion board. • **Reviewing Posting by Peers:** Students reviewed draft annotated bibliographies that were posted by peers and they responded to two postings that they found effective as annotated bibliographies. • **Submitting Draft Paper:** Students submitted their draft paper to the instructor and received her feedback. • **Submitting Final Paper**
Resources Included in Course Guide	**Paper #1:** • "At the Beginning of Constructing Your Paper": a write-up describing what is being expected in the paper. • Video clips of three recent graduates from the Faculty discussing who they are, what they currently do, their connection to the Faculty and their career aspirations. **Resources for:** • Mind Mapping • Outlining • Gathering Relevant **Sources:** • Writing Tips and Exercises • Integrating Sources in Writing • APA Citing and Formatting Guide • List of Readings • Library Database Search Box • Contact Information

APPENDIX 2

Table 2. Blended learning support structure for winter 2012 course

Assignment	**"**In this paper, you are asked to develop and construct your definition of "the determinants of health" by analyzing and incorporating the definitions by others. You are asked to do this by drawing on 6 academic sources." (From the Assignment Sheet of the winter 2012 course.) Students were also asked to use their own words to include summaries of the definitions of others, comparing and contrasting of these definitions, and explaining their personal definition of "the determinants of health."
Course Context	"An introduction to research designs, methods and techniques, as well as the practice of disseminating results, in the context of selected determinants of health. Applications in natural and social sciences will be presented. Skills related to presenting research findings will be taught." (From the course description for the winter 2012 course.)
Online Interactions	• **In-class Twitter instructional session.** • **Brainstorming by Tweeting Twice:** Students were asked to brainstorm what "health" means to them, what one needs to be healthy, or what factors have to be in place to be healthy, during a 4 day period. • **Constructing & Posting a Draft Paragraph:** Students were asked to write a paragraph on their understanding of the concept, "the determinants of health," drawing on the class discussions and course readings. • **In-class library session:** The librarian demonstrated how to search, browse and locate relevant sources for the paper. • **In-class instructional session:** The writing instructor provided instruction on thesis statements and showed how to use the Online Writing Tutor. • **Developing a Draft Outline and a Thesis Statement:** Students were asked to submit a draft thesis statement with an outline to the Online Writing Tutor. • **Posting the Introductory Paragraph and Reviewing Peers:** Students were asked to post their introductory paragraph from the completed paper on the discussion board, then to reply to two peer submissions that they thought were effective as introductory paragraphs.
Resources Included in Course Guide	**Paper #1:** • Paper #1: Assignment Sheet and a general guide to the research paper #1. • "Twittering Instructions": For brainstorming using Twitter and the Twitter live streaming feeds during the brainstorming period. • "Understanding What You are Developing & Constructing": A basic structure expected for the paper was explained. • "Time Management": A timetable of due dates and working with various parts of the paper • "A Feed from the Literature" **Other Resources:** • "Locating Relevant Sources": A reminder for the importance of adequately understanding the purpose of locating the sources, and a summery of what were demonstrated in the in-class library session. • "Analyzing Sources": The instruction on comparing and contrasting the information located in the sources. • "Integrating Sources" • "Using APA" • "Writing Tips" • "Contact Information"

Chapter 31
Blended Learning for Learners in SMEs

Sabine Moebs
Dublin City University, Ireland

ABSTRACT

While blended learning seems to be quite suitable for Small and Medium Sized Enterprises (SMEs), take-up of this learning method is not implemented at the level it could be. This chapter investigates aspects that encourage learners in European SMEs to choose blended learning for professional development. The results indicate how the take-up of blended learning by SME learners can be improved. Research has explored the field further and blended learning has become a more mainstream form of learning. A revisit of case studies with stakeholders of Blended Learning in SMEs looks at changes indicated by research and explores Blended Learning in progress. A comparison between European and African SMEs looks at differences and commonalities that might affect blended learning. The final section outlines a vision of how blended learning is feasible under challenging conditions, including inadequate funding, limited computer or Internet access, poor infrastructure, diversity of learner groups, and differences in learning culture.

INTRODUCTION

Small to Medium-Sized Enterprises (SMEs) are often innovative, but are also under great economic pressure, which is a threat to ongoing learning activities even though continuous training and learning is necessary to stay competitive. E-learning is not in high demand with SMEs although one would expect that it is extremely suitable to a learning demand at short notice (Wood & Watson, 2002), which is typical for SME learning.

Blended learning, a mix of online and face-to-face (F2F) learning, can combine the positive aspects of both, classroom-based learning and e-learning environments (Bonk & Graham, 2006). Blended learning can then provide an alternative to e-learning and might have the potential to better meet SME learners' needs. A mix of learning styles and different dimensions of learning at course level can further increase the usage of blended learning opportunities as a suitable way for training in SMEs and thereby increase or keep up the competitiveness of these companies.

DOI: 10.4018/978-1-4666-8246-7.ch031

The main goal of this chapter is to provide an overview of blended learning, followed by an outline of a vision of how blended learning is feasible under challenging conditions, including inadequate funding, limited computer or Internet access, poor infrastructure, diversity of learner groups, and differences in learning culture.

BLENDED LEARNING

Blended learning describes a learning environment that either combines teaching methods, delivery methods, media formats, or a mixture of them all. The term blended learning is very complex and ambiguous; therefore, the next paragraphs aim to give a comprehensive overview of the different definitions, dimensions, and success factors for blended learning. The following text provides more detail on blended learning topics.

Definitions of Blended Learning

In the literature, the term blended learning is used to describe for example the integrated combination of traditional off-line methods of learning with intranet, extranet Web-based or Internet-based online approaches (Garavan & O'Donnell, 2003). To accentuate the fact that the concept is learner-centered, blended learning can be described as a combination of delivery methods that have been selected and fashioned to accommodate the various learning needs of a diverse audience in a variety of subjects (Mc Sporran & King, 2005). Blended learning combines classroom-based learning with computer-mediated instruction (Graham, 2006; The eLearning Guild, 2006), but it also mixes various event-based activities, including F2F classrooms, live e-learning, and self-paced learning (Valiathan, 2002). More recently the concept of time-based blended learning has been introduced (Norberg, Dziuban & Moskal, 2011). Here the focus is on a mix of synchronous and asynchronous activities. Synchronous activities can be online or in the classroom

The differentiation in skill-driven, attitude-driven, and competency-driven learning as different forms of blended learning looks at the focus of the learning. Skill-driven learning combines Self-paced learning and support mechanisms to develop certain knowledge and skills. Attitude-driven learning aims at developing specific behaviour by mixing different event types and delivery media. Competency-driven learning targets workplace related competencies and provides performance support tools, knowledge management resources, and mentoring (Valiathan, 2002).

The availability of pedagogical expertise, as well as learning delivered through videoconferencing and video streaming in combination with F2F collaboration, is a blend described by the Advanced Broadband Enabled Learning (ABEL) program in Canada (Murphy, 2007). Oliver and Trigwell (2005) dismiss definitions that consider a combination of e-learning with traditional learning, the combination of online learning with F2F learning, the combination of different media, the combination of contents, the combination of theories and learning, the combination of learning objectives, and finally combined pedagogies. They came to the conclusion that blended learning misses the learner's perspective and recommend the variation theory of Bowden and Marton (1998) for the development of blended learning courses to improve learning.

Another approach uses the mix of learning theories towards blended learning, combines cognitivism, constructivism, and performance support which transforms it into a very practical approach defining live events, self-paced learning, collaboration, assessment, and performance support materials as the key ingredients of blended learning (Carman, 2005).

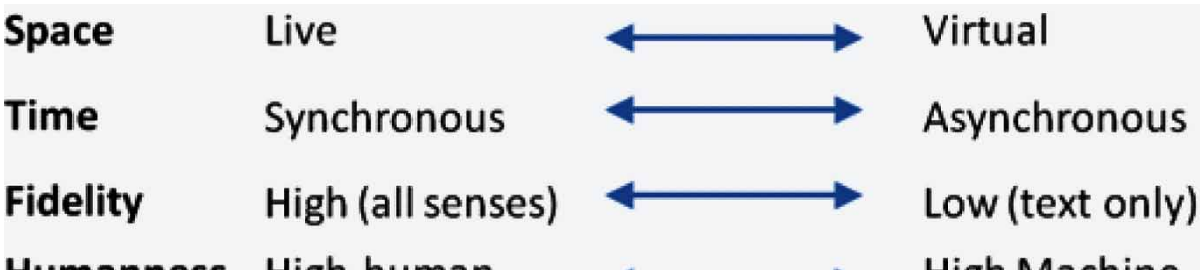
Probably the most succinct definition of blended learning is provided by Reynolds and Greiner, who describe blended learning simply as the "use of more than one instructional methodology" (p. 216). A combination of storytelling, song, recitation, reading aloud, flash cards, puppetry, and corporal punishment is what Cross (2006) adds to the discussion about a blended learning definition with a retrospect to traditional teaching methods. Included in this definition is the remark that most learning is blended in the sense that it always combines different methods, materials, and media. His perception is in agreement with Masie (2006), who goes on by saying that since 1998 the term is widely used for a combination of e-learning and classroom learning. Wagner (2006) describes blended learning as a combination of F2F instruction and computer-mediated instruction. Wagner adds that blended learning always involves content objects and assets, or as Lindquist (2006) stated a combination of classroom and online. This is equivalent to the definition of Wright, Dewstow, Topping & Tappenden (2006), who add traditional distance learning measures to the blend, a definition of blended learning as F2F blended with traditional distance learning (Jung & Suzuki, 2006). The combination of an online teaching environment and F2F lectures leads to a blended learning framework as an approach for open interaction, information dissemination, efficient management or knowledge creation or a combination of all.

A very open definition for blended learning is provided by Ziob & Mosher (2006), who add the aspect of business perspective to the learning scenario. They define blended learning as "any combination of self-paced, instructor-led, distance, and classroom delivery with various digital and print form factors to achieve a positive business outcome" (Ziob & Mosher, 2006, p. 97). Jones also provides a variable definition, but focuses on the degree of technology used in blended learning and distinguishes between basic use of Communication and Information Technology (ICT) and intensive use of ICT. This approach is adopted by other authors, who concentrate on the degree of ICT use and F2F instruction (Lee & Im, 2006; Limon, 2006; Kaur & Ahmed, 2006). ICT use is mainly determined by different forms of e-media (Lee & Chong, 2007) and mode of delivery is typically via a managed learning environment. This environment runs in combination with tutor-led support systems, such as synchronous and asynchronous discussion groups, supplemented by F2F meetings. These characteristics are typical features of blended learning systems (Jones, 2006). The combination of the latest technology and high-skilled human support are the essentials of blended learning (Salmon & Lawless, 2005), or in other words traditional F2F teaching combined with evolving technical possibilities (Henrich & Sieber, 2007). This eventually leads to an evolution model of blended learning. This model starts out with synchronous learning, moves on to the more effective simple blend, and progresses on to rich experience seamless blending to eventually reach performance personalization, the fusion of learning and work as an embedded system, linked with business applications (Singh, 2006). This evolution aims at a continuously improved learning quality: recognizing cost, time, effectiveness and the fusion of learning and work as main settings. Jones coins the term of the 'continuum of blended learning', that describes a continuous increase of ICT use in combination with F2F activities (Jones, 2007). A different terminology is used by Ross and Gage (2006), who describe blended learning either as Web-enhanced or technology-enhanced as opposed to hybrid or reduced and they see the blend on course or program level..

Dimensions of Blended Learning

To describe the variety of interaction Graham (2006) introduced the so-called four dimensions of interaction in F2F and distributed learning environments. The four dimensions are space, time, fidelity, and humanness. Space can range from live or physical and F2F over mixed reality to virtual reality. The time dimension develops from live synchronous, with a very short lag time, to asynchronous, which has a long lag time. Fidelity reaches from a high level that is rich in senses, which means it can incorporate sound, pictures,

Figure 1. Four dimensions of blended learning (Graham, 2006)



text and even fragrances, to a low level, using only one of the senses (e.g. text only). The humanness dimension addresses the ratio of human interaction and machine interaction.

Figure 1 shows the dimensions and also helps to visualize the variety of systems possible within the range described above. All the dimensions can vary between the extreme values, thus providing a huge variety of different interaction settings for the design of blended learning and accommodating the diversity of individual learner needs, learner styles as well as teaching styles.

Frameworks in Blended Learning

Poor design of blended learning material can lead to poor learning results in a blended environment compared to a single method of delivery. Several authors developed frameworks to react to this challenge. Wenger and Ferguson (2006) describe a framework to guide the design and deployment of company training and courses. The framework reflects the idea that most learning environments are blended anyway, considering that even a classroom-only course incorporates a variety of different learning modalities. Their approach consists of three steps. In a first step, the learning ecology matrix is developed. The x-axis illustrates the focus on the delivery of instruction that varies from "content delivery focus" to "experience and practice focus"; whereas the y-axis illustrates the navigation of the learning process that varies from "guided navigation" to "learner self-navigation." In a second step, four general learning modalities are included: studying, practicing, teaching, and coaching. These modalities do not refer to either classroom or e-learning, but are rather applicable to both. In a last step, the matrix is completed with distinct instructional, learning, and knowledge elements. Table 1 shows the framework by Wenger and Ferguson.

The learning ecology matrix aims to deliver a high quality learning experience and at providing control over the learning experience for both the learner and the instructor. It strives to combine formal and informal learning rather than positioning them as opponents. The social nature of learning has to be considered in all learning elements. The aspect of cost-effectiveness is recognized, but merely in the sense that any project aims at a combination of learning outcomes at a minimum total cost.

Another example is the generic framework that was developed by McSporran and King (2005) to enable a structured combination of educational delivery methods. Table 2 shows the generic framework for blended learning.

The framework is intended to provide guidance for the selection of delivery methods, considering the learning needs as well as available resources. Benefits, difficulties, constraints, but also complementary methods are listed to provide the information necessary to develop the right blend. The generic framework is then applied to specific learning needs.

Table 1. Learning ecology matrix (Wenger & Ferguson, 2006)

Studying	Learner Self-Navigation		Practicing
	Books, articles, guides References White Papers Asynchronous content Job aids Glossaries FAQs	Authentic tasks Role play Projects Case studies Peer discussion Discussion forums	
Content			Experience and

Used as a check	Indicates possible challenges to implementation	Provides Ranking for selected method. Used in conjunction with columns D and E	Suggestions of complementary methods

The Mobile Learning Curriculum Framework (Botha, Batchelor, Traxler, De Waard, & Herselman, 2012) is a first attempt to systematically describe how to include mobile learning practice in a blended environment (see Table 3). The framework identifies a basic structure, consisting of a theme as an outline of the domain. A theme contains a number of modules, each module a unit covering a single topic. The module differentiates module rationale, challenges, content and suggested adoption strategies.

Success Factors for Blended Learning

A variety of teaching methods, as well as a variety of different learners with different preferences and needs, determine the success of blended learning. Several success factors have been identified in the literature.

Design of the Blend: A well-designed blend of teaching methods can provide an appropriate learning experience for most learners. The characteristics of the audience must be considered. This

Table 3. Mobile learning curriculum framework themes and modules (Botha, et al., 2012)

Themes	1. The Impact of Mobiles on People, Communities and Societies	2. The Impact of Mobiles on the Economy	3. The Impact of Mobiles on Learning	4. The Nature of the Technology, Systems and Devices	5. Becoming Mobile

					5.4 Agency and Control

includes recognition of the amount of time they will have to access the content, which includes connectivity issues (Bersin, 2003; McSporran & King, 2005).

Time Flexibility: The flexibility in scheduling and a variety of document formats is critical to success. System availability enables students to study when they are ready to do so.

Mix of Media and Learning Styles: The flexibility in media formats provides optimum learning experiences based on personal preference. To select the right methods and formats, the learning styles and the education level of employees must be considered, as well as the motivation of the learners (Bersin, 2003; Serveau, 2004).

Student Support: Response from tutors, subject matter experts as well as technical or logistical support staff should be posted within 24 hours, which corresponds to a rule of thumb for effective e-communication in general. The positive effect of a timely response can be intensified by additional phone calls and F2F conversations and will provide a sense that there exists real people behind the online environment (Serveau, 2004).

Executive Support: Blended learning needs executive support for its introduction, just as any other major change in a business environment. The decision to change to a blended solution from the learning system previously in use needs support from senior management (Serveau, 2004).

Content: The kind and quality of learning content is critical for success. Apart from choosing the appropriate content, which is either intended to inform people, develop skills, or build competencies, it is necessary to ensure that content is up-to-date (Bersin, 2003).

Learning Styles: Another factor for success of any learning system is the consideration of learning styles. There are a variety of different models and theories for learning styles. In engineering education Felder and Silverman's model (1988) is mentioned most often. Research has developed from there, such as the impact on learning styles through Web-based course components (Smart, Kumar & Kumar, 2005) or the implications through research literature (McLoughlin, 1999). Different authors describe the application of the theory of learning styles in computer-based settings (Fenrich, 2006), the incorporation of learning styles in adaptive hypermedia systems (Stash, 2007; Moebs, Piombo, Batatia & Weibelzahl, 2007) and frameworks to adapt instruction to learning styles (Piombo, Batatia & Ayache, 2003). Recently, learning styles and the so-called

Table 4. EU thresholds for SMEs (European Commission, 2005)

Enterprise Category	Headcount: Annual Work Unit (AWU)	Annual Turnover	Annual Balance Sheet Total
Medium-Sized	< 250	≤ €50 million	≤ €43 million
Small	< 50	≤ €10 million	≤ €10 million
Micro	<10	≤ €2 million	≤ €2 million

neo-millenial learners, learners who grew up using interactive media, opened up the area of research on the impact of the use of social software on learning styles (Baird & Fisher, 2006). In a recent publication, Felder describes how learning styles, approaches to learning, and different intellectual development, forms a diversity in students that can only be fully addressed applying different models for each of these aspects (Felder & Brent, 2005).

These success factors of blended learning are valid for SME learners, but they do not consider specific settings of SMEs. The following section provides a closer look at the typical characteristics of and learning in SMEs.

LEARNING IN SMEs IN EUROPE

SMEs are described by business-related thresholds and typical advantages and disadvantages resulting from the company size. A Delphi study was used to explore the problematic issue of training in SMEs and a case study focused on the selection criteria in the Delphi study of the different stakeholder groups.

Characteristics of SMEs in Europe

Continuous learning is crucial for SMEs to foster the continual acquisition of knowledge and to improve their position in the market. SMEs must ensure their employees consistently expand their expertise. According to the European Commission (2007), the main reason for SMEs to engage in training activities is the growing pressure from the internationalization of markets, difficulties in recruiting or retaining staff, as well as, the inability of formal education to match the enterprise's needs. This is further aggravated by other factors such as continuous technological developments, shorter product life cycles, and increasingly demanding customers.

Due to the difficulties of defining SMEs in qualitative terms, we will use a quantitative classification for SME. Quantitative classifications usually apply the criteria "Number of employees," "Annual turnover" and "Annual balance sheet total" to distinguish between small- and medium-sized enterprises. The most recent definition of SMEs according to EU-regulations (European Commission, 2005) is listed in Table 4.

The company size and figures of turnover alone cannot describe typical SME characteristics fully. The Table 5 describes the characteristics, advantages and disadvantages of SMEs and helps to explain what makes their learning situation different from larger companies or small units within multinationals.

SME culture is often characterized by high identification with the business and by a stable environment. Due to the simple structures, any decision usually has very short reaction time. Once a decision is made, another advantage, the cross-functional communication and cooperation within the organisation helps overcome time restriction issues mentioned previously. At the same time, the dependency on a small number of staff puts a lot of pressure and time restraints on these employees. Time management is often neglected or impossible due to sudden demands of company owners.

Table 5. Advantages and disadvantages of SMEs (Baaken & Launen, 1993)

Characteristic	Advantages	Disadvantages
Dependence on a limited number of people (often owners and managers are the same person	Long-term thinking, perspectives Stability No pressure for short-term success High identification with the business, stable culture High commitment	Static thinking, limited to the experiences and the knowledge of the owner(s) Difficulties to adapt corporate culture to new situations and challenges Potential conflicts between corporate objectives and personal objectives of the owner
Close relationships to customers and business partners	Stable basis for further business Ability to cooperate successfully for mutual advantage Ability and willingness to enter partnerships	Risk to focus too much on existing basis of business
Simple structures	High flexibility and adaptability Short reaction times Cross-functional communication and cooperation within the organization	In many cases not suitable for the complex planning and implementing of international activities Low willingness to introduce more sophisticated structures
Small size	Basis for specialization, often successful with niche strategies Innovations and patents	Limited resources (in terms of financial means and manpower) Limited funds to finance investments and initial operating losses for new activities Spending for market research and market entry take a much higher proportion of total spending in SMEs than in larger businesses Limited number of staff to take on additional tasks Lack of internationally experienced employees
Decision maker is owner of the company	Quick decision making High motivation level of decision maker Wide experience	Limited willingness to delegate tasks If owner a person who doesn't take necessary steps, long-term strategy falls behind day-to-day business

Training courses are at times decided upon immediately when the need arises due to a new project, customers or pressure of the market, rather than as part of a sound training strategy. The lack of a general, long-term strategy includes the lack of strategy for development and training. On the other hand, SMEs are often highly specialised. In order to maintain this niche expertise, training is required and therefore provided. Overall it is typical that owners of SMEs rely too much on their own expertise and knowledge and they are prone to ignoring opportunities that staff development can provide (Baaken & Launen, 1993).

One of the well-known problems for learning in SMEs is that it is often not feasible for employees to attend training during working hours (Mungania, 2003). Training costs, including direct expenses as well as costs related to the absence of an employee from the workplace, seem to be too high for many of these companies. Moreover, the absence issue confronts small companies with huge problems, since there are only few colleagues to fill absences.

The need for flexibility and, therefore the option to use quiet periods for training make e-learning attractive for SMEs (Beer, Hamburg & Paul, 2006). This, however, requires a structured approach that enables learning-on-demand as well as corresponding delivery structures which need to be introduced.

E-learning, however, has a number of disadvantages from the perspective of employees in SMEs. Employees tend to interpret the substitution of F2F learning by e-learning as a cost reduction measure and perceive their company is not willing to spend the money for travel and accommodation. Employees also miss the social contact and interaction with other learners as well as the distance necessary to reflect on new topics when learning in their working environment (Beer, Hamburg & Paul, 2006).

Obstacles that make it difficult for SMEs to engage in competence development activities in general are typically:

- Important short-term business pressures (lack of time).
- Cost issues.
- Entrepreneurs' limited ability to effectively diagnose the competence needs or to contact sources of competence.
- Poor quality, extent, and theoretical orientation of the existing supply of formal training and external advice (EC, 2007).

Important obstacles to small business usage of e-learning are lack of appropriate learning materials, the attitude of individual managers, and lack of access to sufficient bandwidth to ensure high quality training (McCullough, 2005). Proliferation of e-learning is limited also by perceived ineffectuality, computer anxiety and a perceived lack of structure and guidance (Wood & Watson, 2002).

In a study on learning and development in Ireland 4 in 10 respondents said that on-the-job training is the most effective form of learning in their organization (CIPD, 2006). Work experience and formal training courses are the next most popular answers for organizations with less than 200 employees.

A Delphi Study on Blended Learning in SMEs

A Delphi study has three main characteristics: structured information flow, regular feedback and anonymity of the participants. The initial contributions from the Delphi participants were collected in the form of answers to questionnaires and their comments to these answers. While in regular group meetings, participants tend to stick to previously stated opinions and often conform too much to a group leader. Participants in a Delphi study are free to change their opinion between rounds, based for example on input from other participants. All participants maintain anonymity. Participants cannot dominate each other in the process by using their authority or personality. This frees them to some extent from their personal biases and helps to minimize the "bandwagon effect" or "halo effect." A Delphi study caters to the individual candidate to freely express their opinions, encourages open critique, and revise earlier judgments if need be.

The Delphi study included three rounds: Round one was used to collect initial input and Round 2 and 3 were used to rounds ask participants to rank the total list of aspects from all participants, select agreement level, and to comment on the definitions for the aspects relevant for learning in SMEs. The study was conducted with a panel of 40 experts, including learners from SMEs, training providers and learners from multinationals to compare the results among the learners. They were selected following a selection pattern. The pattern considers either practical skills as a trainer or knowledge in the area of the research. Learners were selected as experts depending on responsibility for a team of a certain size and experience with blended learning. The participants were asked initially what they consider up to ten relevant characteristics for successful blended learning for learners in SMEs. The study identified the aspects ranked most important over two rounds as well as agreed definitions for these aspects. The participant categories were defined from a blended learning stakeholder definition. A draft category list was then verified by 5 experts in the field as relevant participant categories.

Table 6 shows the preferences of the different stakeholder groups.

The aspects and the definitions which were identified most important by all participants and those selected by the SME stakeholders are provided below. The list contains the definitions as agreed upon by the participants.

Accessibility: 24-hour accessibility of online parts and the option to work from home or while travelling were mentioned. Materials, tutor, IT and classrooms have to be as convenient as possible for the learner to encourage maximum participation. The learner has to be able to decide where and when to learn.

Content Design: Find the most suitable representation. Engage learners with the content as much as possible. Think of interactivity not in

terms of meaningless clicks, but in terms of meaningful interaction with the content. Examples: Sample questions, opportunities for reflection, benchmarking with industry or internal expert opinions, quizzes, simulations, group discussions, role play. All of these techniques engage the learner in meaningful ways with the content - while simultaneously providing interactivity.

Parts of the content are best presented online; others require practical exercise or a face-to-face discussion.

Cost-Efficiency: Blended learning as an option to keep the price of training as low as possible was mentioned. Participants also see a potential to find a good mix by emphasizing the lower-cost elements of the blend (e.g. off-the-shelf e-learning entities, on-line books, etc.). Some participants expressed belief that blended learning often means lower costs. The option to use online course materials for training courses at a regional level with participants in different, often remote locations, is expected to reduce travel costs. In general, participants expressed the opinion that online learning is more cost-efficient both from a short-term, as well as from a long-term perspective.

Efficiency: Learning has to be done in a short time-span so results can be used for productive work immediately. Preparation and wrap-up through online sessions and telephone conferences make face-to-face seminars more efficient.

Gap analysis shows what learning needs to take place. Learning should focus on this gap and not just on what the "general target group" might need.

Suitability of different methods depends on the topic and the training challenge. The efficiency of a method is determined by the person learning, the context of learning and the learning goals.

Blended Learning needs to have more focus on developing the actual needs of the individual and then applying the learning to this need. Too often the effort (money, time) is spent on course content and on delivering the course rather than on the first step. A thorough analysis of the specific learner, her previous learning experience and learning goals will guide towards the right selection of content and learning technology.

Geographical Independence: For the online part we are independent of location as participants can do the online phases without having to leave the workplace. Online components of the blend are generally available wherever the learner has access to the Internet. Some employees are only working part-time and would not be able to spend a full day in a seminar. That makes it difficult to find time for a seminar. Whereas online courses can be attended by employees who are absent as well. It is important that everybody gets the chance to attend, even if they are not present in the company building.

Individuality: Instruction should be designed to adapt to the individual learner and it should provide different kinds of learning experiences. The e-learning enables learners to set an individual focus. Trainers or facilitators need to be able to deal with different personalities and heterogeneous groups.

Learner-Centred: Authentic learning is most effective. We learn best through practicing, applying the principles we are studying, and then reflecting on the experience.

Obviously there is little point in providing a blended learning course that does not meet the needs of the targeted learners. Although this seems very obvious, it is remarkable how often this aspect is neglected. A very clear and precise user needs analysis could be supported by technology. This could be for example a pre-course self-evaluation methodology could evaluate the level of pre-course knowledge existing within the learner community.

Courseware needs to not only address the individual needs of the learner, but it also needs to be relevant to her circumstances and has to be meaningful in relation to her cultural and her linguistic surroundings. Some learning is abstract: therefore, contextualization is critical.

Quality: Subject matter presented must be accurate and authentic. Problem solving and inquiry designs that are presented have to be practiced and reinforced.

Online media can be structured following well-established methods and procedures. Having the online media tested by several testers guarantees a high standard.

The desire is to produce the blend that causes the most effective learning. Whilst the technologies have an impact on the course, the learning design must be solid. Thus the e-learning components must be effective, the stand up trainer must be excellent, the Webinar host stimulating and fluent, and so on. There must be a consistent standard of excellence across all media.

The individual contact, the tutors, the trainers, coaches, mentors, managers, all of these must be flawless in their professionalism. In fact, this is where the personal aspect can make up lightly for any flaws in the components that are purely technology driven, e.g. e-learning.

Both should be able to use new technologies. It does not make sense to offer such combinations to employees who hardly use computers and give these possibilities to trainers, which are not able to trace and analyse the progress of their learners in the electronic system.

The quality of information is relevant; being able to access up-to-date, quality information sources.

Relevance of Content: Courses can be too generic or too specific. Time is a critical factor with SMEs so the course must focus on closing the gap between time required for learning and time available. Having clearly identified learning outcomes and an agreement on the learning outcomes provides an implicit agreement on the relevant content.

We all learn best when we have a good reason to learn. People are not very motivated to learn things they do not need at the moment or to learn facts that are not up-to-date.

Look for methods of capitalizing on the "wisdom" of the workforce.

Any Content needs to be as apt to individual trainee's needs as possible. Learning must be relevant and useful to the learner, otherwise it is just an exercise soon to be forgotten.

Results Measurement: It is important that the assessment and results measurement is solid, reliable, and accurate. Frequently, this is not considered sufficiently as an element in the blend. Feedback to the tutor enables her to assess the knowledge level among participants. In contrast to pure e-learning, the tutor can react to difficulties of the learner on an individual basis during face-to-face sessions.

Quick error checks - learning success or mistakes can be highlighted easily. Online programs enable quick check of learning results.

Self-Paced Learning: One needs to learn self-paced learning. A lot of learning is simply presented to students rather than letting them explore it themselves. Provide learning and practice experiences that are available over a continuum of time, versus all within a short timeframe. Spaced learning and practice helps cement new knowledge into long term memory, and provides additional cues for retrieving the knowledge and skills under different circumstances. Self-paced courses enable participants to select the order of topics and modules. The pacing of the learning process is placed to a certain extent with the student and can suit their time needs and commitment. Self-paced learning is suitable for shift workers and those on time constraints who may not be able to attend a conventional timetable class or course. Blended learning's main benefit for students and employers is the flexibility to do the course at your own time and pace.

Student Interaction: The ability to interact at different levels and through different media should allow a more adaptive approach to learning. Participatory opportunities for students to have a voice e.g., using Voice over IP was mentioned several times, but also taking the student through a number of learning routes rather than a given sequencing of learning materials.

Support Mechanisms: Personal support for every participant by mail, phone or chat, or mentoring is considered important. Collaboration tools are seen as possibilities to greatly improve the team work that can be allocated and performed. The ability to work in teams or virtual teams is perceived as a supporting function. Providing ample opportunities for students to obtain help with specific problems was mentioned as well as the need to explore topics that might be a little off the curriculum. The online assessment is considered helpful for motivating the learner, because it gives immediate feedback. Nevertheless, social interaction in the classroom is also required.

Time Flexibility: Trainers and participants should have the time to get to know the system and the combination of online and face-to-face teaching and learning. Online learning should allow learning when it suits the learner and moreover enable completely independent learning. It should enable participants to decide on learning times suitable to other activities and to use times in between normal work. Online learning should support the learner in making best use of their own time.

Usability: The access and the registration for the trainee to a course should be easy. Nothing keeps more people away from online training than tedious registration processes.

Formal learning is guided by an instructor. If the guidance is not working then frustration replaces learning.

The platform should be easy to use. Only username and password should be required to log in.Perhaps it is the length of time required in projects that perspective sometimes gets lost, but clear navigation is critical.

Most online platforms to attend so called "Webinars" are too complicated to use. Logging in takes up to 15 minutes because you need to register, get an email, enter the registration code, and call the company in the states, and so on.

Workplace-Related Learning: The course needs to be relevant to the skills or the information gap of the organization. Learning content has to be up-to-date and important to the user.

Due to the nature of the Delphi study as an explorative study, the results must be read as qualitative rather than quantitative results. The study results give an overview of what was considered important by the different stakeholder groups. This does not mean that aspects not selected among the most important aspects are not relevant.

The ranking-type Delphi aims at finding an agreement between groups through a ranking of self-selected issues. Initially the panelists are asked to list five to ten important aspects of blended learning. Participants have to add a description and a rationale for putting the item on the list. The total input from round 1 is consolidated into a list size short enough to be accepted by the participants in the next round. The panelists rank their "Top 20 Issues," ties not allowed from the n-item list from round 1. The results of this second round are aggregated into a list of "Top 20" items for each sub panel. This 20-item panel specific list is presented in the third round as a list of the "Top 10" with ranks from ten to one. All other items on the list (11-20) are equally ranked "0." The panelists rank their "Top 10" issues from the 20-item list in the third round. The rank is calculated by combining percentage of mentions and relative rankings by the individual panelists.

The results did not change significantly throughout the three rounds. This shows that they are fairly solid. Mostly aspects were defined more clearly or expanded throughout the rounds.

Recommendations for Blended Learning in SMEs

The results from the Delphi show that SME learners put a balanced emphasis on the area design, skill-driven learning, the access to knowledge, quality assurance and cost effectiveness. A successful blend has to keep a focus on those areas. The preference for a blend varies depending on the industry and the size of the company. A comparison of the sub-panels IT and tourism SMEs shows that Tourism SME learners rate the importance of social interaction much higher. The large companies sub-panel chose clearly different areas, compared to the IT SME sub-panel. There was a strong emphasis on design and social interaction, whereas cost effectiveness was not considered as important.

These results give some indication to which preferences exist among SME learners, while these preferences might not be reflected in the results of any of the other groups involved in the study, e.g. trainers or learners in multinationals. Providers can apply these aspects for their product development. For example "student interaction" is among the top 10 from the provider sub-panel, whereas the SME sub-panels did not select the social interaction- related aspects at all. SME learners prefered feasibility and individuality. This gives some indication that providers should include feasibility and individuality as requirements for their development in addition to features that enable student interaction.

Trainers put a strong focus on design-related aspects, which are not in high demand with the SME sub-panels. Support mechanisms and self-paced learning are much more important to the learners according to our results. Emphasizing the support and enabling self-paced learning should not replace the design aspects. But if in doubt, the SME-selected aspects should be preferred. The results show that providers and trainers interested in blended learning for SMEs have a highly different view on the topic. There is an opportunity for SMEs to get into a dialogue with providers, and trainers where possible, to change their approach to blended learning. This might not be feasible for the individual SME; however most companies are members of professional organizations and can transport their view of the topic through these communication channels.

Another option would be openness towards new learning technologies. A lot of the implementations that enable, for example the individuality of social interaction or the time flexibility for access to knowledge are based on new technologies, often Web 2.0-based. Openness to using these learning technologies can easily bring together the diverging approaches of SME learners and trainers or providers.

LEARNING IN SMEs IN AFRICA

One goal of this chapter is to explore which of the results from the study can be transferred from the European to an African context. Clearly the situation is different on both continents, but there are still similarities in the context of SME learning that allow comparison and experiences that are worth sharing.

SMEs in Africa

A quantitative definition for SMEs from South Africa describes SMEs in similar parameters as the European definition (see Table 7).

EU and African definitions for SMEs are very similar. Headcounts are within the same range and although the South-African annual turnover and the South-African annual balance sheet total

Table 7. Thresholds for SMEs for EU (European Commission, 2005) and Africa (Government Gazette of the Republic of South Africa, 2003)

Enterprise Category		**Headcount: Annual Work Unit (AWU)**	**Annual Turnover**		**Annual Balance Sheet Total**	
Medium	Africa	50-200	≤ €4.2 million	≤ ZAR 51m	≤ €1.6 million	≤ZAR 19 m
	Europe	< 250	≤ €50 million		≤ €43 million	
Small	Africa	1-49	≤ €1.1 million	≤ ZAR 13 m	≤ €0.4 million	≤ ZAR 5 m
	Europe	< 50	≤ €10 million		≤ €10 million	

are much smaller once converted into Euro, the absolute numbers are almost the same, e.g. annual turnover for medium-sized companies ≤ €50 million and ≤ ZAR 51 million.

A comparison of the characteristics from Table 5 shows that most characteristics similarly define SMEs in Europe and South Africa. The most significant characteristics are the dependence on a limited number of people, close relationships to customers and business partners, and the decision maker being the owner of the company (Fatoki, 2011). SMEs in Europe suffer from a deficiency of formal education to match the enterprise's needs, while in South Africa a lack of education and training lead to reduced management capacity in SMEs (Olawale & Garwe, 2010).

A recent study found that SMEs in South Africa are negatively impacted by a number of obstacles, mainly related to economy, markets, infrastructure, and management (Olawale & Garwe, 2010). While the first three obstacles are external, management is an internal factor that cannot be influenced much by the individual SME. Main internal management factors are control of finance, managerial competency of the owner, selection of location, decision on investment in information technology, cost of production and networking. The lack of managerial experience and skills, as well as lack of education and training are the main reasons for SMEs to fail (Olawale & Garwe, 2010).

Learning Environments

While in Europe Technology-Enhanced Learning (TEL) is still mainly based on PCs and laptops, TEL in Africa often relies on the use of mobile phones. Mobile phones are more widespread than PCs and laptops in Africa and thus enable smore people to participate in education and training. Therefore blended learning in the African context is seen as a mix of events in a classroom and on the mobile phone. This blend is suited to the reality of many African SME learners and is also seen as a trend for future blended learning elsewhere, with mobile devices, particularly tablets, replacing PCs and laptops more and more worldwide. The following section looks at the learning environment, considering infrastructure, ways to improve access to learning, obstacles to learning, and new concepts to overcome of the challenges presented.

The main challenges for the introduction of mobile learning initiatives are infrastructure, learning theory and cost (Adesope, Olubunmi & McCracken, 2007). Infrastructure is being built across the African continent and continuously improves accessibility of the Internet and mobile resources. Internet access has improved a lot during the last 5 years, resulting in decreasing costs for operators and end users. This happened mainly due to a number of projects for an undersea backbone in the Indian Ocean, in particular EASSy, TEAMS, and SEACOM. EASSy (East African Submarine cable System) is a 10,000km submarine fibre-optic cable system that connects Mtunzini (South Africa) and Port Sudan (Sudan), with landing points in Mozambique, Madagascar, the Comoros, Tanzania, Kenya, Somalia and Djibouti on the eastern coast of Africa since 2011. TEAMS (The East Africa Marine System) is a submarine fibre optic cable project of the Kenyan government. SEACOM, is a privately owned and operated pan-African submarine cable operator, serving the East and West coasts of Africa.

Mobile devices, in particular smartphones, are becoming more affordable for larger parts of the African population and many experts predict there will be smart phones and tablets available below the $60 (Aker & Mbiti, 2010; Jidenma, 2011). The first examples of these available phones came on the market recently with the Huawei Android IDEOS, Nokia Lumia 710, or the African-designed VMKTech Android phone and tablet (VMKTech).

Learning theory is a challenging topic as well. Much of the mobile learning is based on collaborative learning. However, teachers and trainers are often not sufficiently prepared to accommodate this form of learning and teaching (Adesope et al., 2007). Trainers and teachers could gain these skills using new learning formats, for example Massive Open Online Courses (MOOC) or collaborative learning scenarios like the Reconstructed Living Lab (R-lab) in Cape Town, South Africa. Both learning formats will be introduced below.

Access is the Key – Open Educational Resources (OER) (Wright & Reju, 2012), open source software, open access publications and Web accessibility will enable access on many different levels relevant for blended learning. OER and open source allow access in several ways. Both, software and educational resources can be legally shared and adapted, depending on the users needs. Open access publications are not hidden behind costly subscriptions, but available for all interested readers. The consideration of Web accessibility (W3C-WAIa) not only includes users with different abilities, but makes online resources better usable across different devices (W3C-WAIb). The learner is free in her decision of the learning content and the device used to access learning.

Many of the learners cannot assign time during their workday, but they spend time travelling to work in public transport or have time resources at home after work (GSMA & MasterCard, 2011). Better available online material will address the need of this large learner population who has to juggle work and study and finds it difficult to attend many sessions in a classroom. Relevant educational material available through mobile phones will allow these learners to improve their skills. This can be informal, work-related learning like CV advice, language learning, or technical documentation. The material on the mobile can tie in with TV and provide a multi-screen educational material. While the TV was named as information source by 43% in a recent study (GSMA et al., 2011), mobile learning is associated with savings in time, because it is cutting out travel and rather allows using travel time for learning. It saves money, because by its nature it is often an alternative to private learning institutions. Nevertheless classroom time is helpful, but it is also precious, for aforementioned reasons.

The concept of the flipped classroom is moving collaborative activities into the classroom while delivery of materials is done outside classroom time (Butt, 2012). Classroom time can be used for collaborative work, rather than collecting new information. Collaborative Fearning Classroom learning can happen in new forms of collaboration like living labs or "Learn with Grandma." "Learn with Grandma" is a small, not-for-profit company based in Wales, UK. They promote intergenerational learning, often an exchange of knowledge how to use technology and more traditional skills. Living labs, for example R-Labs in Cape Town, South Africa initiate knowledge exchange with the goal to impact, empower and reconstruct communities through innovation. Both initiatives build on students who will continue learning by turning into teachers themselves. The living lab example of the Reconstructed Living Lab (R-lab) in Cape Town (Parker, Wills & Wills, 2012) combines an academy with community development and incubation. They provide courses for entrepreneurs and social innovators using a play and learn approach. The iHub in Nairobi is a community of technology entrepreneurs and an openspace workspace (iHub, 2013). Learning happens continuously between members of the community in informal and formal sessions, supported by their iHubResearch group. All these collaborative forms of working and learning tie in with the "on-the-go" mobile learning. Massive Open Online Cources (MOOC) (Koutropoulos & Hogue, 2012) is a form of self-directed learning and requires the learners to be very proactive. Learners are expected to actively feed into a learning community. Most MOOCs are heavily based on OERs and are therefore available for everybody with access to the Internet. MOOCs and mobile learning can be combined successfully (Traxler & Leach, 2006). In combination with one of the collaborative learning forms above they can be a suitable blend for SME learning, because the open format of a MOOC allows focusing on parts of the course that are of most interest. SMEs can use this learning format in collaboration with other companies with similar learning needs. Subjects that allow for a sufficiently broad learner base, e.g. accounting, project management, communication skills or even basic digital literacy are suitable.

Sustainable learning models have to consider the physical environment of the learner, which can be quite challenging for SMEs in Africa. Office buildings and study rooms might only provide limited learning infrastructure, such as furniture, books, electrical light and poor mains electricity. There might only be one computer with Internet access available, which limits opportunities to share and upload materials. The mobile phone can balance out some of these challenges, in particular ICT skills can be learned and taught using the ubiquitous mobile phone. Many learners with very little experience with a mobile device can figure out how to use a mobile phone in a short period of time (Traxler & Leach, 2006) and will quickly start learning using educational games on mobile phones (Greenop & Busa, 2008).

Obstacles for blended learning using mobile phones are the pricing strategies of the Internet providers. Feature phones provide a lot less features and therefore less comfortable learning than the much more expensive smart phone. It still requires a bit of learning moving from feature phone to smart-phone. A stronger commitment to m-learning in the mobile industry could solve many of the obstacles mentioned (GSNA & MasterCard, 2011; Mahai, 2012).

A VISION FOR THE FUTURE OF BLENDED LEARNING

In 2020 SME learners can rely on simple access to education, based on community learning groups or classroom sessions combined with a vast array of mobile and online learning material. The learning materials are mostly OER, covering skills and subjects like digital literacy, communication, bookkeeping, health and safety, as well as specific and technical material. The course materials are a mix of resources authored for the specific learning needs, adaptations of existing OER, new creations, often as user-generated content and they are distributed and sourced world-wide.

Smart phones are affordable for everybody. Due to competitively priced data packages everybody who owns a mobile device can learn. Blended learning combines mobile learning and (flipped) classroom sessions. The terms m-learning, e-learning and blended learning have disappeared. People are learning with whatever device or method is available and the learning systems are flexible enough to allow everybody to start at the appropriate level. This allows learners, including those in SMEs to use short learning sessions on their way to work or during breaks, waiting for customers, spare parts or other similar situations.

For those who cannot sit down somewhere with their phone, the audio Web provides a good way to access all the materials through their mobile phone only. Learning on mobiles uses audio clips, e-books, Web links, and study guides. On a smart phone, learners can get learning support, hints, tips, revision material, polls, and quizzes.

Learning material is available at any time for self-paced learning, but for more structured learning MOOCs are offered. They can be used for programs to gain certificates. People can learn in small steps as it fits into their life. Bi-weekly face-to-face training sessions cater for the need of exchange with other students and the facilitators. These sessions are filled with task-based collaboration, question and answer sessions, discussions and, sometimes, they can be used for exams as well. Certificates can be gained by sitting for an online exam. Modular degree courses allow counting these certificates towards the degree. Online exams can be taken anywhere, as long as some official verifies the identity of the person logging in for the exam. The flipped classroom sessions are preceded by individual learning, usually via the smart phone. People learn at home, on their way to work at work, whenever they need to know something. or when they have ten or fifteen minutes to dive into a short learning session.

The biggest change has happened in company culture. Management in small SME encourages employees to learn and has put incentives in place for those who educate themselves or use organized courses. Well trained staff, educated through formal or informal learning, is encouraged to continually update their knowledge.

CONCLUSION

This chapter has presented a variety of definitions and dimensions of blended learning. These are mainly concentrating on a variety of teaching methods and their delivery mode, in particular a mix of online learning and face-to-face teaching. The chapter has introduced blended learning frameworks and outlined the main success factors. These are primarily a designed mix of media and learning styles, time flexibility, and support mechanisms. A study analysing requirements for successful blended learning in SMEs showed that time flexibility, cost efficiency, support mechanisms, accessibility, efficiency, quality, self-paced learning, results measurement, content design, and learner-centeredness are most relevant.

The applicability of those concepts to small and medium-sized companies varies between Europe and Africa, due to the different geographical, economical, and cultural circumstances. However, company size results in a number of similar characteristics in European and African SMEs, which allows applying the results. One outstanding common characteristic is the lack of education and training. Taking into account recent changes of the technical infrastructure and the general prevalence of mobile devices in Africa the actual implementation of blended learning will focus more on a mix of m-learning, rather than PC-based learning and face-to-face learning. This will enable learners, wherever they are and will give access to education and training as required.

KEY TERMS AND DEFINITIONS

Blended Learning: A mix of learning methodology, learning technology, and delivery methods. It is most often a mix of different learning technology suitable for face-to-face and classroom parts of a course.

Feature Phone: Simple mobile phone that allows sending short messages, making phone calls, saving short notes, and storing addresses in an address book.

Massive Open Online Courses (MOOC): MOOCs are online learning environments aiming at a large, often worldwide online audience interested in one particular topic area. They are often using OERs, but this is not mandatory. Some of the key benefits are depending on large numbers: high interactivity in forums, related blog posts, and online conference discussions. More information: http://mooc.ca/ or http://mobimooc.wikispaces.com.

M-Learning: Mobile learning, using mobile devices, typically mobile phones, feature phones, but more often smart phones and tablets. Mobile learning uses the typical user scenarios of mobile devices and integrates them for learning. This is in particular, messaging, listening to audio clips, reading texts, discussions, taking pictures,and feeding into social media (blogs, Twitter, Facebook).

Open Educational Resources (OER): Educational resources which can be used, adapted. and shared. They are usually protected with a Creative Commons Licence. More information: http://creativecommons.org/education.

Small and Medium-Sized Enterprises (SME): SMEs have characteristic advantages and challenges because of their size. They allow for quick decisions, are often highly specialized, but can also lack defined work processes and a strategic approach to market challenges.

Smartphone: Mobile phones with more advanced features than a feature phone, like reading emails, going online, using dedicated mobile applications for a number of online and offline activities. Overall its scope is closer to that of a laptop than a feature phone.

Chapter 32
Active Learning in the Flipped English Language Arts Classroom

Clarice Moran
North Carolina State University, USA

Carl A. Young
North Carolina State University, USA

ABSTRACT

This mixed-methods research study examines the engagement of high school students in a flipped English Language Arts (ELA) classroom. The students were enrolled in two sections of an Advanced Placement English Language Arts and Composition (AP Lang) course and were in the 11th grade. Forty-nine participants answered questions on a validated survey, and 8 participants took part in 2 focus groups. In addition, a researcher observed the flipped classroom and took field notes. Quantitative survey data was analyzed through STATA statistics software, and qualitative data was transcribed and coded. The results of the data analysis indicate that students had mixed feelings about the flipped method and its implementation in an ELA classroom. Survey data indicates general support for the method's principles but revealed mixed attitudes toward it as a method of instruction, especially in terms of it as a strategy for addressing all instruction in the ELA classroom. Qualitative data indicates that some students felt more engaged by the flipped method, while others did not. The results of the research indicate that the flipped method might be effective, in part, in an ELA classroom, but not as a sole means of instruction.

INTRODUCTION

Much is being made about the flipped model of instruction as a major reform initiative with the potential to reshape teaching and learning. Journals, newspapers, conferences, websites, podcasts, and blogs all tout the benefits of this new pedagogy as a paradigm shift that is reshaping learning and will reshape the classroom environment, reaching even the most reluctant of learners.

Teachers in English language arts (ELA) classes have begun using the flipped instructional model as a way to deliver fact-based content in a focused and efficient manner. Although there

DOI: 10.4018/978-1-4666-8246-7.ch032

is scant research on the efficacy of the model in the ELA classroom, a handful of teachers across the country have begun using the method in an attempt to better engage their students and, ideally, effectively address the curriculum. Their reasons are similar to those used by teachers in other content areas: they want more one-on-one time with students (Fulton, 2012); they want a classroom centered on inquiry and problem-based learning (Bergmann & Sams, 2012a); and they want to eliminate the constant homework struggle (Strayer, 2007). This chapter will provide a review of relevant literature and research and also present the results of an independent research study on the flipped method conducted in a high school ELA classroom. In addition, it will discuss the advantages and disadvantages of using the flipped method in an ELA environment and will highlight strategies, activities, technologies, and tools that might be a part of an effective flipped ELA classroom.

Although many English teachers have attempted to incorporate new technologies into their classrooms using an integrated framework, such as TPACK (Koehler & Mishra, 2009), others have used Web 2.0 tools and the Internet in an attempt to "tick the box" on technology use and follow the guidelines for technology use in the new Common Core State Standards (CCSS). Although technology is one component of the flipped classroom, educators who want to integrate the method into an ELA classroom must ensure that the curriculum is driving the technology, not the other way around (Shelly, Gunter & Gunter, 2012). We believe that a flipped classroom is but one component of a well-stocked, ELA pedagogical toolbox. English teachers may choose to adopt or reject the strategy, as well as technological integration in general (Swenson, Young, McGrail, Rozema & Whitin, 2006). The research study presented in this chapter demonstrates that the combination of technology and a new pedagogical method can be engaging for students but should be implemented with intention, forethought, and care.

BACKGROUND

Making the Flip: The Origins of the Flipped Classroom Model

The "flipped classroom" moniker can trace its origins to the frustrations experienced by a university professor in a small, private college in Ohio (Baker, 2000). After noticing that his communication students were simply copying verbatim from PowerPoint slides without processing the information, Professor J. Wesley Baker at Cedarville University decided to post the PowerPoint slides onto the school's new computer network and have the students read the slides before coming to class. His idea, launched in 1995, was to use four key concepts to drive the model. The concepts were: "clarify, expand, apply, practice" (Baker, 2000, pp. 13-14) in order to shift his role from "sage on the stage to guide on the side" (Baker, 2000, p. 9). The students reviewed the material on the slides before class, and Baker (2000) then clarified and explained the concepts at the start of class, expanding on the basic information in the slides. The students broke into small groups to apply and practice the concepts. Baker (2000) surveyed his students at the end of the term and discovered that they felt they had learned a great deal from their peers through the collaborative activities. He dubbed the new process the "Classroom Flip" and presented a paper on the idea at a conference in 2000.

Simultaneously, another group of university instructors at Miami University in Ohio launched an "inverted classroom" (Lage & Platt, 2000) in an attempt differentiate their microeconomics lessons for different learning styles. The availability of technology was the spark that ignited the idea and allowed the researchers to turn the traditional classroom environment on its head by asking students to view PowerPoint slides and course content on a course website before coming to class. Once in class, the students worked in small groups to analyze the material. Lage, Platt and Treglia (2000) wrote that "inverting the classroom means that events that have traditionally taken place inside the classroom now take place outside the classroom and vice versa" (p. 32). A survey administered at the end of the course indicated that students enjoyed the collaborative nature of the class and valued learning economics in a new way. The researchers concluded, "students generally preferred the inverted classroom to a traditional lecture and would prefer to take future economics classes using the same format," (Lage, et al, 2000, p. 41).

A few years later, in 2007, two high school chemistry teachers in Colorado began a collaborative effort to teach their content with the aid of screen capture software that allowed them to record lectures and spend class time working one-on-one with students (Bergmann & Sams, 2012a). Their idea was born independently of Baker's (2000), but seemingly created from the same primordial goo of the 21st Century: technology access and frustration over students' lack of engagement. Anecdotal evidence suggested that the Bergmann & Sams (2012a) method was successful, so the pair began touting its benefits through conferences, blogs, and a website. They have since moved the basic flip idea into a "Flipped Mastery" concept (Bergmann & Sams, 2012a, pp. 51-93) in which asynchronous learning takes place as students work simultaneously, but at different paces, on multiple projects. Bergmann & Sams (2012a) believe the flipped classroom model has tremendous potential to reduce the frustrations of teaching, because (among other things) it personalizes education, increases student-teacher and student-student interaction, and makes the classroom content transparent to parents and others.

Higher Education and STEM as the Focus of Flipped Research

Since the inception of the idea, others have attempted this paradigm shift in their own classrooms in an effort to "reach every student in every class every day" (Bergmann & Sams, 2012a, book title). The flipped method has become the hot topic with regard to education in the media, garnering significant attention in newspapers (Barr, 2013) and journals (Bergmann & Sams, 2012b; Berrett, 2012; Fulton, 2012; Tucker, 2012). Yet, almost all of the published research to date has been conducted exclusively in Science, Technology, Engineering, and Math (STEM) classrooms – and most of these studies were conducted at higher education institutions. To complicate matters further, much of the data has been inconclusive, as students and teachers cannot quite decide if they like the new method or not, or decide if it is effective enough or not.

In one mixed-methods study, J.F. Strayer (2007) compared two introductory statistics classes that he taught. One class was taught using the traditional lecture format, while the other employed the flipped method. Strayer's framework leaned on Activity Theory and active-learning theories posited by Vygotsky (1978) and Dewey (1990), which speculated that students learn best through activity and physical engagement with the content. Strayer (2007) used a video series to deliver the lecture content to his flipped class and followed up with activities and collaborative learning during class time. Both his quantitative and qualitative data found that students in the flipped classroom were less satisfied with the instruction they received. Although students in the flipped class were found to prefer collaboration and innovative teaching strategies, they said they felt less connected to the professor and that class time felt redundant after learning the content from a video. Strayer (2007) concluded that the students did not really know "how to do class" (p. 155) and that frequently the collaboration felt like "the blind leading the blind" (p. 135).

However, in another study, the flipped model outscored the traditional classroom paradigm in terms of student satisfaction with the course, as well as academic achievement. The study, conducted by Marcey and Brint (2012) in two introductory biology classes at a private university in California, compared the Cinematic Lectures and Inverted Classes (CLIC) model to the traditional lecture model. Students in the CLIC class outscored the traditional class on all quizzes and tests in the first half of the semester. By the second half of the semester, however, the achievement gap had closed between the groups. The researchers posited that this was because students in the traditional lecture class had begun watching the videos too – an interesting finding that led them to conclude that the videos, not the collaborative activities, were the key to success in the class.

Other studies at higher education institutions have not shown such clear preferences for the flipped model. In a study conducted by Ferreri and O'Connor (2013) in university-level pharmacy classes, students demonstrated improved grades and learning outcomes in a class that emphasized collaborative learning over traditional lectures. However, the students in the non-traditional class turned in course evaluations that were more negative than those in the traditional class.

A study in two university-level computer science classes found that students in a flipped class demonstrated high levels of engagement, compared to the traditional class (Gehringer & Peddycord, 2013). The students in the computer science flipped class watched videos for homework, then collaborated during class time while the instructor circulated among the groups and answered questions. The students reported enjoying working with a partner to talk through material, but they did not score as well on the final exam as those in the traditional lecture class.

Secondary Schools Context

A study conducted in a high school also indicated mixed results from using the flipped method of instruction. Johnson and Renner (2012) used a mixed methods switching replications design to study two, 12-week high school computer classes. One class was flipped; the other was traditional. Students were randomly assigned to each class, and then they were switched at the half-way point. This way, students experienced both methods of instruction within the 12-week period. The researchers measured the success of the instruction through the cognitive levels of questions asked by students. They used Bloom's Taxonomy to assess the cognitive level. The researchers concluded that there was no evidence to support higher satisfaction with the flipped method and no significant difference in academic achievement. In fact, they found that there were more higher-level questions asked in the traditional class. However, Johnson and Renner (2012) remained cautiously optimistic about the flipped method at the end of their study, noting the following:

If a teacher is driven to implement the flipped approach and is willing to commit to the extra work required in order to ensure success, content area should not be a significant factor. Future research on determining the efficacy of the flipped method of instruction should only be conducted when teachers realize the need for drastic change in instructional practice and are willing to tackle the drawbacks associated with time, student work ethic, personal work ethic, technology access and history (p. 67).

Other data on the flipped method is anecdotal, but indicates promise for the strategy. In a high school calculus class, student proficiency with course material increased after their teachers adopted a flipped method (Fulton, 2012). In a middle school in North Carolina, teachers reported that student engagement and test scores increased after implementation of the flipped classroom in math and social studies (Barr, 2013). And nearly 99% of 453 teachers surveyed who implemented a flipped classroom said they planned to repeat the approach during the next school year (Flipped Learning Network, 2012).

FLIPPING THE ELA CLASSROOM

There is great interest among educators in the flipped classroom method at all grade levels and in all subject areas. However, there is a dearth of research published on flipping the classroom in the elementary grades, as well as at the middle- and high-school levels. Since the pedagogy is new, many educators are simply trying it without the aid of empirical evidence. To date, there appears to be no published research on the flipped ELA classroom yet – at any level – and, according to the National Center for Academic Transformation (NCAT), dozens of colleges and secondary schools are using the method anyway. This means that ELA teachers interested in implementing the method must rely on their own ideas for adapting the strategy or consult resources from conferences, workshops, websites, or word of mouth to construct their flipped lessons. As such, the paradigm shift of the flipped classroom may be in jeopardy of not having a viable or lasting impact. As Tucker (2012) explains, "Given education's long history of fascination with new instructional approaches that are later abandoned, there's a real danger that flipping, a seemingly simple idea that is profound in practice, may be reduced into the latest educational fad" (p. 83). Tucker's warning highlights the need for more research on the flipped model in all content areas at all levels, but especially for ELA.

Framework for a Research Study in a Secondary ELA Classroom

To address the lack of research in secondary schools and ELA classrooms, we conducted a mixed-methods independent research study in two 11th grade English classes. Our purpose for the study was to assess student engagement with the flipped classroom method in a secondary ELA classroom and to add to the body of research about the flipped method. We used a theoretical framework based upon Kearsley and Shneiderman's (1998) Engagement Theory for technology and learning, along with the principles of TPACK (Koehler & Mishra, 2009). In addition, we viewed a flipped ELA classroom as being reflective of Dewey's (1897) beliefs about the importance of creating new attitudes and new interests in pedagogical methods. In his seminal work *My Pedagogic Creed*, Dewey (1897) states, "The progress (of education) is not in the succession of studies, but in the development of new attitudes towards, and new interests in, experience." In effect, students are engaged with, motivated by, and learn from compelling interactive educational experiences.

Student engagement as defined by Fredericks, Blumenfeld and Paris (2004) is a three-pronged concept:

1. **Behavioral Engagement:** "Draws on the idea of participation," as well as active involvement in the activities of the classroom;
2. **Emotional Engagement:** Includes the student's "positive and negative reactions" to the academic subject; and
3. **Cognitive Engagement:** Reflects the student's willingness to put forth effort and consider higher-level concepts (p. 60).

We viewed student interest, or engagement, in the flipped classroom as being composed of all three concepts. We measured behavioral and emotional engagement through field observations in the classroom. In addition, we used a survey based on a modified version of the Computer Attitude Questionnaire (CAQ) originally developed and validated by Knezek and Christensen in 1996 to assess middle-school students' attitudes toward learning with computers. Beeland (2002) adapted the CAQ to measure student engagement in interactive whiteboards.

In addition, Kearsley and Shneiderman (1998) developed an Engagement Theory that posits students learn best when using technology in conjunction with collaborative, project-based learning. The theory states that technology is a vehicle that helps drive the learning and heighten student engagement, while collaboration and project-based curricula allow students to reach higher levels of cognitive understanding. Kearsley and Shneiderman (1998) write:

Engagement theory is presented as a model for learning in technology-based environments which synthesize many elements from past theories of learning. The major premise is that students must be engaged in their course work in order for effective learning to occur (p. 23).

We felt it was important to measure student engagement, as defined by Fredericks, et al (2004) and Kearsley and Shneiderman (1998) in our flipped classroom study because students who are engaged are more likely to succeed in school and less likely to drop out (Connell, Spencer & Aber, 1994). In addition, students who are more engaged in a flipped classroom than in a traditional classroom may be more likely to have positive academic outcomes, since there is a strong correlation between participation/behavioral engagement and academic achievement (Finn, 1989; Finn, 1993).

In our study, we used technology in our flipped method as an additional tool to help interest students. However, we did not want the technology to simply be an "add on" (Koehler & Mishra, 2009), but rather a different way to excite students and keep our pedagogy fresh. Our intent was to use the TPACK framework (Koehler & Mishra, 2009) as a means to inform the integration of technology so that students engaged more fully with the course material. Since TPACK describes an integration of technology, pedagogy, and content knowledge, we hoped the use of technology in our flipped classroom would help engage students. We aimed to blend content knowledge with our new pedagogical approach and technology.

Our research questions for the study were:

1. Are high school ELA students engaged by the flipped classroom method? If so, what aspects of the strategy appeals to them as students? If not, why not?
2. Do high school ELA students prefer the flipped classroom paradigm over the traditional classroom paradigm? If so, what aspects of the strategy inform their preference? If not, why not?

Sample

A purposeful convenience sampling method was used in the study. The participants (n=49) were students in two class sections of an Advanced Placement English Language and Composition (AP Lang) course at Pinewood High School, a suburban high school in the Southeastern United States. Pinewood has a student population of more than 2,000 students in grades 9-12. The school is located in a semi-rural area and is comprised of 46% African Americans, 37% European Americans, 14% Hispanic Americans, 2% Asian Americans, and 1% American Indians, according to a county report on gender and ethnicity. In addition, county school system records show that about 47% of the students at Pinewood High School are eligible for free or reduced lunch.

The 49 student participants in the sample were largely of European American decent with 39 European Americans, 8 African Americans, 1 Asian American, and 1 Hispanic American. The students were enrolled in the AP Lang course, which is an advanced course that focuses on rhetoric and composition in English. Students self-select the course and are not tracked in, or placed, in the course by counselors or former teachers. All students enrolled in the year-long course, however, must be aware of the increased rigor and workload related to the content. The course culminates in a standardized exam administered by the College Board in May.

We chose to conduct our study in the AP Lang classes because we felt that students enrolled in the course would be highly motivated and more likely to complete the flipped method's requirements. Since students choose to take the rigorous course, we hypothesized that they would be motivated to engage in the new method. In addition, Ms. Brown, the teacher for both sections of the course, offered her classroom as a testing ground for the flipped model. Ms. Brown distributed informed consent forms prepared by the researcher to all students (n=52). Forms signed by parents were returned by 49 students.

Method

In our study, Ms. Brown was instructed on how to implement the flipped method, which we interpreted to mean inverting the classroom so that direct instruction and lectures took place outside the classroom and activities related to the instruction took place inside the classroom (Baker, 2000). In other words, the homework that normally would have taken place outside the classroom was completed during class time, while the lecture and direct instruction that normally would have occurred during class time was completed at home.

Using Jing screen capture software to record lectures, Ms. Brown implemented the flipped method with her students twice. We hypothesized that students might be confused by the inversion during the first flip and would need a second flip to gain comfort and practice with the method. The students were instructed to view for homework the videos Ms. Brown created with Jing and uploaded to her class website. The students were directed to take notes on the videos and then come to class prepared to participate in activities related to the video content. The researcher was present for the creation of the first Jing video, as well as for field observations during both implementations of the flip. At the conclusion of the second flip, a survey was administered to students. In addition, the researcher met with two focus groups of 4 students each (n=8) to discuss their feelings about the flipped method. The researcher also met separately with Ms. Brown to discuss her observations on the flipped method.

Survey data was analyzed quantitatively through STATA statistics software. Focus group comments were audiotaped and then transcribed. The comments were open coded (Creswell, 2013) and analyzed for similarities, differences, and common themes. We felt that a mixed-methods approach was best for our study as it allowed the researcher to "strive to understand the meaning people have constructed about their world" (Merriam, 2002, p. 4). In addition to gathering the quantitative survey data, we were interested in field observations and conversations with students as a means of triangulation. Creswell (2013) described this type of qualitative research as being naturalistic in that researchers gather multiple forms of data in the field, not in a lab setting.

Survey Instrument

The survey instrument we used to measure student engagement in the flipped method was a modified version of the validated CAQ (Knezek & Christensen, 1996). Like Beeland (2002), we used the instrument to measure student engagement in a specific method of instruction. Beeland (2002) used a modified version of CAQ to investigate student engagement in interactive whiteboards. The survey we used consisted of the same 20 questions used by Beeland (2002) with the language modified to reflect the flipped method, rather than an interactive whiteboard. The dependent variable as measured by the survey was student engagement in the learning process. The independent variable was the flipped classroom method.

Students (n=49) responded to the survey questions on a Likert-type scale from 1-5. A response of 1 indicated that the student "strongly disagreed" with the statement; 2 indicated the student "disagreed"; 3 signified the student was "undecided"; 4 indicated the student "agreed" with the statement; and 5 indicated the student "strongly agreed" with the statement. Table 1 displays the questions on the survey, as well as the means and standard deviations for the responses.

Procedures

The First Flip

Ms. Brown is a veteran teacher with a Master's degree and more than 10 years teaching experience in ELA. She is enrolled in a Ph.D. program in education at a major research university. She was only vaguely familiar with the idea of the flipped classroom, but was open to learning more about it. The researcher met with Ms. Brown during a teacher workday and went over basic principles and ideas behind the flipped classroom, as defined by Bergmann and Sams (2012a) and Baker (2000). Ms. Brown decided to implement the first flip during a unit on writing research papers. She said that she had struggled in previous years to get students to adhere to the Modern Language Association's (MLA) guidelines on formatting papers, notecards, and Works Cited pages. She wanted to try the flipped method for instructing students on how to create notecards for a research source. She opted for the free Jing.com screen capture software after debating the benefits of filming herself on camera. She said she did not feel comfortable in front of a camera and preferred the voice-over capabilities of Jing. With the aid of the researcher, she downloaded the free Jing

Table 1. Questions from student survey with means and standard deviations

Question	M	SD
1. I enjoy learning with the flipped method of instruction	3.27	.81
2. I do not like receiving instruction through the flipped method	2.82	.97
3. I will be able to learn more material if my teacher uses the flipped method	2.80	.87
4. I concentrate better on the lesson when I watch an instructional video for homework	3.12	1.05
5. I enjoy watching videos very much	3.55	.94
6. I would work harder if I could learn through the flipped method more often	2.73	.88
7. I know I can learn many new things when my teacher uses the flipped method	3.02	.80
8. I enjoy watching an instructional video for homework	3.27	.97
9. I enjoy the chance to work on my own in class	3.65	.97
10. I believe that the more often teachers use the flipped method, the more I will enjoy school	2.80	1.0
11. I believe that it is very important for me to be able to learn through video lectures	3.02	.99
12. I feel comfortable with learning through the flipped method	3.53	.84
13. I get a sinking feeling when I think of learning through the flipped method	2.39	.86
14. I think that it takes a longer amount of time to learn when my teacher uses the flipped method	2.76	1.05
15. Learning through the flipped method makes me nervous	2.20	.96
16. Using the flipped method is very frustrating	2.41	1.02
17. I will do as little work as possible when my teacher uses the flipped method	2.41	1.02
18. Learning through the flipped method is difficult	2.20	.76
19. Independent learning does not scare me at all	3.83	.96
20. I can learn more from a live lecture in class than from a video at home	3.59	.98

Note: High school ELA students (n=49) responded to questions on a Likert-type scale from 1-5.
1=strongly disagree; 2=disagree; 3=undecided; 4=agree; 5=strongly agree.

software and recorded a lecture on formatting notecards for research papers. Through Jing, she was able to demonstrate precisely where citations and information should go on the cards. The Jing software limited her lecture to five minutes, which she found constraining. She had to re-record the lecture several times to accommodate the time limitation. Afterwards, however, she remarked that the time limit forced her to be more concise and specific, and she thought that was a positive quality.

Ms. Brown uploaded the completed research card video onto her classroom website. She instructed students the next day that they had one week to watch the video and take notes on it. She also gave all students an accompanying handout with specific guidelines on making notecards. The students were told that they would have class time in the school media center to find sources for their research papers and complete their notecards. Ms. Brown told them she did not plan to give further instruction on how to create notecards, but that they were to use the video, the handout, and each other as resources.

On the day the students were scheduled to complete the notecards in the media center, the start of school was delayed due to snow. One class was able to complete the cards as scheduled. The second class did not go to the media center until the following week because of the weather-related shift in the school schedule. The researcher was present as an observer in the media center during both classes and observed student interactions and comments. Ms. Brown reminded students that they should have watched the video for homework. She also told them that they could watch it on the media center computers during class time if they were unable to watch it at home. At the end of the class periods in both classes, Ms. Brown instructed each student to hand in a minimum of five notecards and one citation card. The results of the correct notecards were recorded.

The Second Flip

For the second flip, Ms. Brown felt comfortable with the Jing software and recorded a lecture by herself on how to annotate a primary source. Annotation of primary sources is a key skill for AP Lang students, who must quickly discern the meaning of certain words and phrases for the AP Lang exam. Teaching annotation is one of the skills recommended by the College Board for AP Lang teachers.

Ms. Brown's second Jing video provided a lecture on the importance of annotation, as well as a demonstration on how to annotate a primary source document. Ms. Brown uploaded the video to the class website and instructed students to watch it for homework. Students were told that they would be expected to demonstrate mastery of the annotation skill in class and that they should take notes on the video to aid in their retention of concepts.

In the classroom, Ms. Brown presented the students with a document and instructed them to annotate it and write an essay. The researcher was present as an observer in the classroom as the students worked. On this flip day, both class periods were able to meet on the same day. During the last 10 minutes of the class period, Ms. Brown directed students to listen to the researcher. The researcher then read a prepared statement to the students, instructing them to fill out a survey on the flipped classroom method. The flipped classroom method was defined in the statement, and students were told that their responses were anonymous. The students completed the survey in class and then deposited completed surveys in a bag that sat on a desk at the front of the room.

The Focus Groups

The researcher returned to Pinewood High School about a week after the second flip had been implemented. At this time, Ms. Brown selected four participants from each class for a focus group discussion with the researcher. Ms. Brown's stated aim in selecting participants was to choose students of differing genders and racial/ethnic backgrounds, as well as ability levels. The students from the first class period met with the researcher in a conference room next to Ms. Brown's classroom. The students in the second class period met with the researcher in another teacher's classroom.

FINDINGS

In our study, we wanted to determine if high school ELA students were engaged by the flipped classroom method. We conducted a mixed methods research study in two AP Lang classes to determine the extent to which students found the flipped method engaging. We administered a survey to the participants (n=49), spent time in field observations, and conducted two focus groups of students. In addition, we talked with the teacher to determine her thoughts and reflections on the flipped process. Our results were mixed. Survey data indicated that students were engaged with the flipped method and liked it as a form of instruction, but remained unsure about whether it was superior to a traditional lecture model. Field data and focus group data indicated that students were polarized in their support of the method, with some students strongly supporting it and others intensely disliking it.

Survey Data

Survey data indicated that students enjoyed the flipped method and found it engaging, although they were unsure about its effectiveness as an instructional method that might be used exclusively. The questions on the 20-question survey can be divided into three main classifications:

1. Independent learning;
2. Comfort with the flipped method; and
3. Belief in the efficacy of the flipped method.

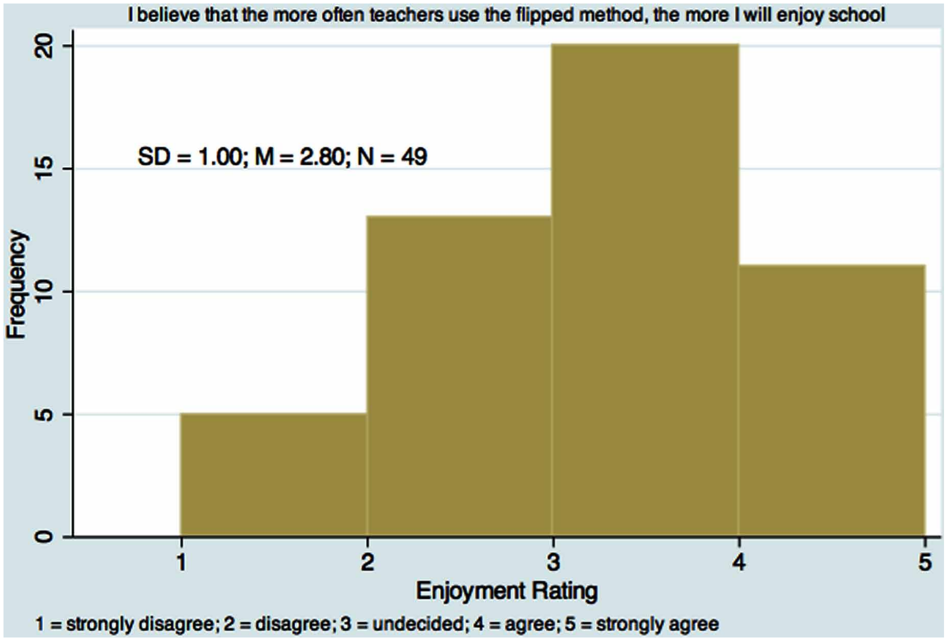
Student responses indicated that most students enjoyed the opportunity to learn independently and work on their own without direct instruction from their teacher. In addition, responses indicated that most students felt comfortable with the flipped method and enjoyed the chance to view lectures and direct instruction on a video. However, responses showed that students were unsure about the efficacy of the flipped method and were undecided as to whether it was superior to the traditional lecture model.

In regards to independent learning, student responses to question 9 ("I enjoy the chance to work on my own in class") indicated support for this statement (M=3.65; SD=.97). In addition, responses were highly supportive of question 19 ("Independent learning does not scare me at all") (M=3.83; SD=.96). These high ratings may be reflective of the type of students who sign up to take an Advanced Placement course. Most of these students are highly motivated and are probably more inclined to need less support or structure to learn.

In regards to comfort with the flipped method, student responses indicated that most students were unafraid of the method and open to learning through it. Survey responses indicated agreement with question 12 ("I feel comfortable learning through the flipped method") (M=3.53;SD=.84). In addition, a large number of responses indicated agreement with question 1 ("I enjoy learning with the flipped method of instruction") (M=3.27;SD=.81). Likewise, there was disagreement with question 15 ("Learning through the flipped method makes me nervous") (M=2.20;SD=.96). This comfort level may be indicative of the "digital native" (Prensky, 2001) status accorded to 21st Century teenagers, who have grown up with a wide array of digital tools at their fingertips and may have developed a mindset that makes them more open to new innovations.

In regards to belief in the efficacy of the flipped method, student responses indicated that many were unsure whether it was an effective

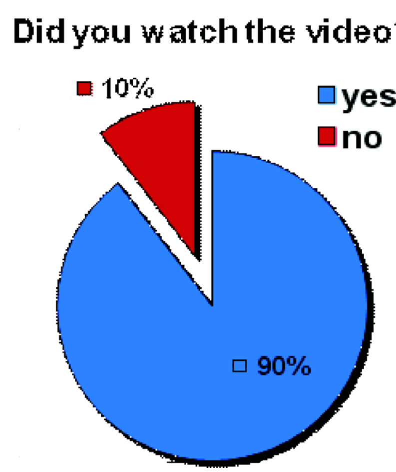
Figure 1. Histogram of responses to question 10



pedagogical strategy and some disagreed that it was an appropriate tool. Responses indicated disagreement with question 3 ("I will be able to learn more material if my teacher uses the flipped method") (M=2.80; SD=.87), as well as disagreement with question 10 ("I believe the more often teachers use the flipped method, the more I will enjoy school") (M=2.80;SD=1.00). And, perhaps, most telling of all, responses indicated agreement with question 20 ("I can learn more from a live lecture in class than from a video at home") (M=3.59; SD=.98). With the strategy being new to the students and with their not having many prior opportunities to weigh in on their perceptions of teaching strategies, it does make sense that they are undecided at this point. Figure 1 indicates the responses to question 10 with means, standard deviations, and frequency counts.

The vast majority of students indicated on the survey that they did watch the video for homework. Figure 2 shows the percentages of students who watched the video.

Figure 2. Percentage of students who watched the video for homework

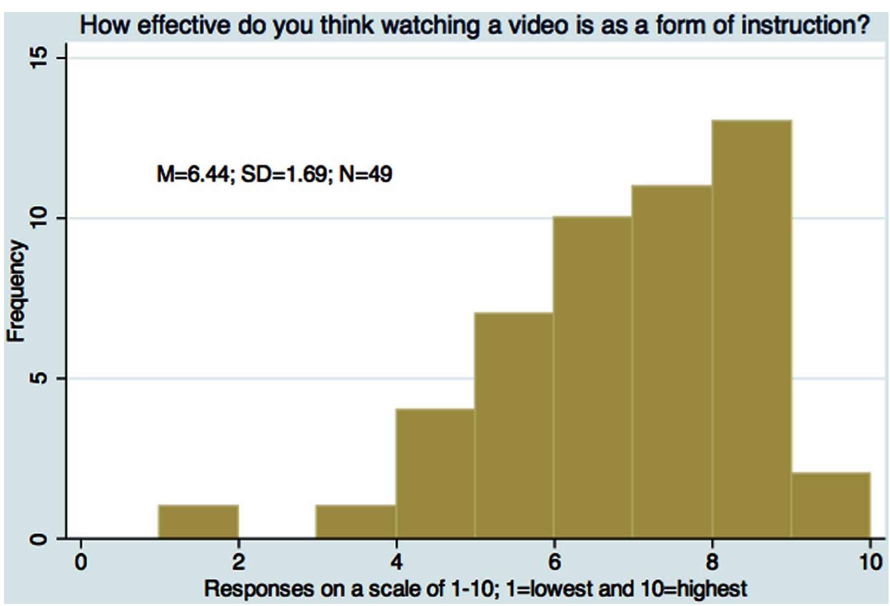


Lastly, we included one item on the survey that was not on the Beeland (2002) survey or on Knezek and Christensen's (1996) original CAQ survey. We also asked students the following: "On a scale of 1 to 10 – with 1 being the lowest and 10 being the highest – how effective do you think watching a video is as a form of instruction? Write your number." Student responses indicated a moderately high level of belief in the efficacy of the method, with a mean of 6.44, standard deviation of 1.69. This is a finding that is inconsistent with the other survey data. This question was asked before the other survey questions, so the early placement on the survey may have caused some respondents to change their minds by the time they got to the last question. It might also indicate a discrepancy in their perceptions of how they learn on their own or at home versus how they expect to learn in school or on school-related tasks. Figure 3 indicates the student responses.

Qualitative Data

Two focus groups were held with a sample of students (n=8) from both classes. The first focus group consisted of two males and two females. In the first group, one student was African American; the other three were European American. The second focus group consisted of three females and one male. In the second group, two students were African American, and two students were European American. All students were selected for participation in the focus groups by Ms. Brown, who chose them based on ethnicity, gender, and ability level in order to hear a variety of student voices. In addition, the researcher observed the students in the flipped classroom on four separate occasions and took field notes. The researcher also interviewed Ms. Brown in a private conference room. The findings from the qualitative data supported those of the quantitative data. Students had mixed feelings about the flipped classroom method and were nearly polarized in their responses to it. Some students seemed to enjoy it, while others actively disliked it. One student attributed this discrepancy in attitudes to learning styles. Nicole remarked that she was not a visual learner and did not like having to rely on the visual components of the Jing video to learn a new concept: "For the reading thing that we have -- I had some questions about it. If [Ms. Brown] would try to explain on the video, I would have some questions. My learning style is not visual."

Figure 3. Histogram of student responses to efficacy of videos as instructional tools



The responses from the focus groups and the observed field data were coded and analyzed for theoretical similarities and differences (Creswell, 2013). Five main themes emerged from the data analysis regarding students' perceptions of the flipped method:

1. **"I like the flipped method:"** Class time is more productive, and I can rewind the homework videos.
2. **"I prefer traditional classes:"** I don't like the flipped method, and I want lecture-based, traditional, teacher-led instruction.
3. **"The flip is impersonal:**" You have to rely on yourself, and collaboration with other students is difficult.
4. **"The flip is not good for English class:"** Discussions and deep, theoretical concepts are not appropriate for the flipped method.
5. **"I don't care:"** School is still school, no matter what method you use.

1. "I Like the Flipped Method"

Students who said they liked the flipped method said they enjoyed the ability to rewind the video that Ms. Brown made and listen to it repeatedly until they understood her message. Students also said they liked being able to work on their own or in small groups and not sit through long lectures that might run off-topic during class. Students said they enjoyed the "to the point" aspect of the flipped method and were able to come into class and get to work immediately on the activities. They also commented that lectures in a traditional class sometimes were derailed by student questions. In the flipped method, Ms. Brown was able to be concise and precise without interruption or unnecessary tangents.

Student responses to the survey question "I do not like receiving instruction through the flipped method," indicated that a majority disagreed with the statement (M=2.82; SD=.97).

From the teacher's perspective, Ms. Brown said she enjoyed the flipped method and likely would use it again. She said she thought the students were more on-task during class time and that more class time was devoted to doing the activity than to her explaining and re-explaining what was required. At the end of both periods in which the students made research notecards, the completion rate of correct cards was much higher than in previous years, according to Ms. Brown. She explained further:

Before, when I explained it in class, they would ask questions and not even look at the handout. Now, they tell their friends they didn't do their homework, but they don't want to admit to me they didn't do the homework. So, if anything, it's forcing them to be more self-reliant and ask fewer questions about how to do it.

Students who said they liked the method seemed very enthusiastic about it and were clear that they preferred the flipped instruction over a traditional class. As Jake said, "I think it's perfect, because you come into class with the knowledge of what's going to go on in class." Other students, like Sadie, said the ability to listen to something repeatedly and find answers to their own questions was their favorite aspect of the model: "I liked that we could go back. Like, instead of ask questions, you could go back and listen to it again if you didn't understand."

2. "I Prefer Traditional Classes"

Likewise, students who said they did not like the method were very vocal about their dissatisfaction. Those who did not like it said they missed the discussion-based format of a traditional English class. The flipped classroom involved more student-to-student interaction and less student-to-teacher interaction. This was a negative aspect for some participants, who felt that deep concepts would be missed without the teacher's direct instruction. In addition, they said they found watching a video tedious and tiresome and preferred the animated teaching style of Ms. Brown. On the survey, a majority of students disagreed with the statement, "I would work harder if I could learn through the flipped method" (M=2.73; SD=.88).

Keisha explained, "I feel like sometimes when you watch a video, you get tired of sitting there. It's hard to focus on the video for so long. And then, in the classroom, it's just hands-on and it can be more involved. And you already have to be there." Danny added, "It's funny, because I can sit there and play with my phone all day. But when I had to watch the video, I was like: 'Is it over yet? How many minutes?' It's like my concentration span for that is not good."

When asked how they would feel if their English class was taught via the flipped method all year, students who disliked the pedagogy said they would "quit" or "switch classes" and said they did not think they would learn as much. Juan explained, "I think I prefer traditional, because the way it is normally, I think that being taught in class and going home, homework is generally trying to see if you understood and can apply what you've learned in class at home. I think in the flip, you might not learn as much."

Juan's statement was corroborated by survey data, which indicated a majority of students were undecided when it came to the statement "I know I can learn many new things when my teacher uses the flipped method" (M=3.02; SD=.80).

3. "The Flip is Impersonal"

Students relied heavily on each other to complete correct notecards and annotations. This self-reliance caused some students to react negatively to the flipped method. Marcus said, "As far as doing anything at length, like an entire unit, I feel like it would become too impersonal in a way. The teacher is not there, hands-on teaching you, and they also take your questions as they come to you."

Survey data indicated that most students were undecided or agreed with the statement "I can learn more from a live lecture in class than from a video at home" (M=3.59; SD=.98).

During field observations Ms. Brown was observed to answer an average of 11 individual questions during a 10-minute period, or slightly more than one question per minute. Students appeared visibly frustrated with having to wait their turn for her attention, and a couple of students sighed loudly and dropped their raised hands with a loud slap onto their desks. In addition, Ms. Brown answered some of the same questions repeatedly as she went from student to student. During the 90-minute class period, she did not sit down once. Although Bergmann and Sams (2012b) have indicated that they enjoyed communicating individually with each student and felt a more personal connection in a flipped classroom, Ms. Brown reported some annoyance at having to run around her classroom repeatedly to answer individual questions.

The students also expressed some concerns. Danny commented, "When she made the videos, they're relatively easy to understand, but I watched them like three or four times so that I could take the notes on them. And I don't have that problem usually. So I don't know what it is. Maybe it is just better to have a person talk directly to you."

4. "The Flip Is Not Good for English Class" (Or Is It?)

Most students were new to the flipped method, but one male focus group participant said he had also experienced it in an Advanced Placement biology class. The method worked well in biology, Juan said, but he did not think it worked as well in English, because English required more discussion and reflection. Other students echoed this idea, remarking that English class was the one subject area in which yes-no answers did not always apply and that discussion was important. They said the unique nature of ELA made the flipped method unsuitable for every unit. Instead, simple lessons that required more quantitative thinking, such as research paper formatting or grammar instruction, would be the only aspects that would be effective in a flip because of "the questions and the confusion."

Juan explained further:

I don't think English in a video form is very interesting. I know it wouldn't be the same thing with math, because that's always interactive when you're going through a question. Or in science, where you're watching a video that [teachers] would go over in class. I know that those two things would normally be in a video, and the teacher might say, "Go watch this. Prepare for the next day." But English... it's kind of in its own realm. It takes, like I said, a little more personal connection on the information you're going over at that time. Because questions arise at that time that aren't really explained the way a math problem or a science video would explain something.

Ultimately, students provided insights into the types of content material that might be better suited for the flip strategy rather than seeing the strategy as a method to be used exclusively in the ELA classroom.

5. "I Don't Care"

Lastly, a small number of students said they actually did not care which pedagogical method their teacher used. In the end, it was all just school to them anyway. This group said that the excitement and newness of instruction on a video was not the same as "watching a video with kittens" or some other short, high-interest, entertaining video they might find on YouTube. The short, five-minute time frame of Ms. Brown's Jing videos felt "too long" for these students, who said they struggled to watch the entire lesson.

Most of these students said they would "just deal" with whatever instructional method their teacher chose. They remarked that they felt "neutral" toward the flipped method and did not prefer it over the traditional classroom method, but that they didn't "hate it" either. "It's not horrible," Keisha said. Another student, Rachel, said she did not watch the video, although the method might work if she cared more. She said, "It sounds like it would be a really good idea, but in reality I didn't do it. I'm just really apathetic."

On the survey, a majority of students disagreed with the statement "I believe that the more often teachers use the flipped method, the more I will enjoy school" ($M=2.80$; $SD=1.0$), possibly indicating that no instructional method would provide school enjoyment. Although this is a source of frustration for teachers, it is important to note that even the best instructional methods may not promote school enjoyment for older teenagers.

DISCUSSION

Overall, the students seemed to have mixed feelings about the flipped method of instruction and did not embrace it whole-heartedly as a pedagogical strategy for the ELA curriculum. In regard to research question 1 -- "Are high school ELA students engaged by the flipped classroom method?" – the data indicated that students are engaged by the method. Many reported that they liked the opportunity to work at their own pace. Survey data revealed that students felt the flipped method was not difficult and that they liked watching an instructional video for homework.

In regard to research question 2 – "Do high school ELA students prefer the flipped classroom paradigm over the traditional classroom paradigm?" – the data indicated that students were mixed in their preferences of classroom paradigms. Many students said they preferred the lecture/discussion model that is already employed in ELA classes and that they would learn more from a live lecture in class than from a video at home. Students also voiced the idea that discussions are the best method of instruction for English classes, but that the flipped method may be more engaging for science and math classes.

Issues, Controversies, Problems

As discussed previously, the flipped classroom method is a current educational innovation that many see as a means for transforming teaching and learning in the 21st century and beyond. Describing the "right way" to flip a classroom is a tall order, however, as advocates for the method have devolved into individual camps whose methods for implementing the flip are not always consistent with each other. Some proponents believe that the method is one tool among many from which a teacher can choose. Others posit that the flip must be implemented in every class, every period, all year long in order to have the lasting impact intended.

One major issue teachers must consider before implementing the flip in ELA classrooms is the types of lessons and content information that they want to cover. In our study, students said repeatedly that they did not believe discussion-based formats should be abandoned in an ELA course. In particular, high-level courses, such as the AP Lang course in our study, benefit heavily from discussions. Students indicated that they enjoyed the opportunity to hear other students' ideas and thoughts. They also said they valued teacher-led, whole-class discussions, since student-led group discussions occasionally lose focus or reinforce faulty information. As Keisha said: "I feel like in small groups, you get off topic, and you don't focus on what you're supposed to. You need the teacher." In addition, working in isolation may run contrary to the overarching intent of studying the humanities, which involves understanding what it means to be human, as well as connecting with others. Without the collaborative aspect of discussions, students' responses implied that they might miss the intangible benefits of higher-order thinking, as defined by Bloom's Taxonomy.

Another issue to consider is the encouragement of active collaboration. This gets to the heart of Engagement Theory (Kearsley & Shneiderman, 1998), which advocates for a pedagogical model based on students actively being able to "Relate-Create-Donate" (p. 20). In this model, students "relate" to one another through collaboration and discussion; "create" through project-based learning; and "donate" their efforts to the community at large or to an "outside customer" (p.21). Simply working on individual activities, even in the asynchronous learning environment promoted by Bergmann and Sams (2012a), may not be enough to fully engage students in the ELA classroom.

Lodge McCammon, a specialist in Curriculum and Contemporary Media at the Friday Institute for Educational Innovation, conducts workshops for teachers interested in using the flipped classroom method. McCammon advocates for a paradigm shift in which as many lessons as possible are taught in a flipped environment. He instructs interested teachers in ways to alter their teaching, typically in lessons that last about one to two months. Many teachers elect to continue with the flipped method over the course of the school year. McCammon believes using the method on occasion is not sufficient enough to gauge student interest and increase engagement. In his workshops, he encourages teachers to flip their classroom as often as possible. He also advocates for an environment of asynchronous learning in which each student is engaged in his or her own project and goes at his or her own speed.

We have observed some ELA teachers successfully implementing the flipped principles in the majority of their lessons who continue to preserve some aspect of whole-class and small-group discussions. Troy Cockrum, a middle-school ELA teacher in the Midwest, has produced blogs and podcasts, as well as presented at conferences on his version of the flipped classroom. Cockrum has successfully implemented the flip for two years and is a strong proponent of asynchronous learning. However, he says that he prefers to leave some class days for book discussions, and his students enjoy this, as well. The benefits of teacher-led discussion in an ELA classroom cannot be underestimated, he says. In addition, Cockrum believes students need to be guided gently into the flipped method: "Kids need to know what's expected. Kids might be confused in the beginning." Although many students might be nervous about the flipped strategy initially, Cockrum has found that they adjust quickly.

Other issues to consider before flipping are access problems, as well as technological failure. Although we did not encounter any students who claimed to have a problem with computer or Internet access during our study, some participants said they "knew of" students for whom access could be a problem. Any flipped lesson that relies too heavily on Internet access could be doomed for failure. In fact, in Cockrum's ELA class, the school's Internet system went down for approximately 20 minutes during a 40-minute class period due to heavy snowfall. The students, who previously had been engaged in asynchronous learning projects, were unsure of what to do and began to walk around the room and consult with one another. One student said, "Since the Internet's down, I really can't do much. What are you guys going to do since the Internet's down?" The students discussed a birthday party and made "cootie catchers" instead. When the Internet came back up about 20 minutes later, a student shouted, "It's back! It's a miracle!" As with any well-planned lesson, a teacher is going to want to have contingencies, but this seems to be especially true when planning with technology.

SOLUTIONS AND RECOMMENDATIONS

There are several recommendations for teachers interested in implementing the flipped method in an ELA environment. First, teachers should work to introduce the method to students before relying on it as a primary means of instruction. In our study, and in our other observations, we found that students were apprehensive about the method initially. However, as they became more comfortable and more familiar with it, they were able to process the instructions better. After our first flip, some students remarked that they thought the method was "stupid" and did not watch the homework video. After the second flip, however, more students said they liked it and seemed less confused by the implementation in the classroom.

Second, teachers should keep videos to a maximum of 5 minutes. Some flipped proponents have advocated for videos between 5 and 10 minutes, but in our study and observations, we found that students begin to lose interest after about 2-3 minutes of viewing of time. Teachers who want to make certain students are viewing their instruction should write out a script for their lesson, and then condense it to less than 5 minutes for the video. Jing.com, as used in our study, is one tool for making a screen-capture video. In addition, PowerPoint offers an online commentary feature for teachers who would rather record comments over an existing PowerPoint. The most successful videos, however, may be those that feature the teacher's face. Research is ongoing in this area.

Third, students should be expected to demonstrate in some way that they have understood the concepts or instructions presented in the video or flipped instruction. One teacher we know of who uses the flipped method has all students turn in "something" by the end of every flipped class. Students must be held accountable and not see the flipped method as a way of getting by without working. Bergmann and Sams (2012a) recommend that every student come to class with a question about the video, the message to students being that they are going to be held accountable for viewing the video. Teachers can ask students to take notes while watching the videos and turn in these notes or have students post the notes on a class blog, wiki, or Google doc. This is another way of making students responsible for doing the homework associated with the flipped method, and if the teacher has them post to a shared space, it also helps to engage students in a shared community as well.

Young and Bush (2004) suggest a three-step process for introducing technology into the English classroom. This model involves:

1. Developing a pedagogical framework;
2. Asking the important questions; and
3. Establishing working guidelines.

With this in mind, we suggest a process for introducing the flipped paradigm into the English classroom:

- Develop a unit of study
- Determine the end goals
- Design the instruction

Develop a unit of study: The unit of study chosen for the flipped paradigm should involve project-based learning and student-led instruction. This model works well in an English class, as many of the instructional units already rely heavily on project-based learning. We suggest a short, one- or two-week unit as a way to introduce the concept to a classroom. Suggestions include: a unit on poetry; drama; genre studies; a single novel or non-fiction text; or essay writing. This unit may be a unit that is currently being taught through traditional methods, such as teacher-led instruction.

Determine the end goals: Most good, preservice teaching programs suggest that teachers must start with the end in mind. This is good practice for a flipped unit, as well. Determining the summative assessment, as well as general objectives, is an important aspect in implementing a flipped classroom. Teachers should ask themselves: If all students are working on something different at the same time, how will I know when they have met my objectives?

If, for example, the chosen unit to flip is one on poetry, how will the teacher know when students have met his/her goals? Are the goals clearly stated at the beginning of the unit? Should all students know specific literary terms or types of poems? Are the goals tied to local standards or the Common Core State Standards? Are all students required to create a poem? Should students be able to identify specific poetic language? Once the end goals are established, the individual aspects of instruction can be determined.

Design the instruction: In a flipped English classroom, students will have additional time to write (Bergmann & Sams, 2012a), as well as work on individual or collaborative projects. We advocate for a mix of both collaborative and individual assignments, as this allows for maximum differentiation. Teachers may choose to record instructional videos for the unit, and then assign them to students as homework. Troy Cockrum, the teacher in the Midwest, posts videos to his class website and allows students several days to view them. In our study, Ms. Brown also posted instructional videos to her class website and gave students several days to view them. When students have viewed a video, they should provide some evidence that they have watched it. This could take the form of notes they hand in or a verbal question/comment they tell the teacher. Our research indicates that students should be made accountable for watching videos.

Inside the classroom, students can work on activities designed by the teacher to further enhance their understanding of the topic and to meet the goals and objectives of the unit. Here is a sample outline for a two-week unit on poetry in a 7th grade classroom, suitable for 45-minute periods.

Before the unit: Teacher creates three videos about poetry. The first video is a 5-minute lecture of the teacher talking to the camera in his/her classroom and writing on his/her white board as if students were in the class. The lecture is on different types of poetic forms and their characteristics. The second video is a 5-minute voice-over lecture on figurative language and includes a screen capture shot of defined terms. The teacher talks over the screen capture through the Jing.com software. The third video is a 5-minute lecture on writing with the five senses, created by a PowerPoint voiceover.

Day one:

1. Explain the flipped classroom.
2. Introduce the poetry unit.
3. Assign three videos for homework for the week. (All videos must be watched by the end of the week. Students should bring in an index card with one interesting fact they learned – or a question they had - from each video by the end of the week.)
4. Watch a ready-made video together as a class. This video is one that has been created by another teacher, such as Troy Cockrum (see resources); the teacher models taking notes on the video by rewinding and pausing as he/she writes down important facts. (For example, see a short video on writing a limerick poem here: http://www.youtube.com/watch?v=UKMGd_uNlbE.)
5. Put students into groups and distribute a poem to each group for reading and analysis. Each group creates a poster that visually illustrates the feelings and main concepts behind the poem, based on the video information.

Day two:

1. Distribute handouts with individual projects for students to complete. The individual work includes: listening to an audio recording of a poem and writing a reflection on it; reading a poem by a famous author and completing a graphic organizer to analyze it (poems can be differentiated for ability); creating a poem of student's choice (e.g.,, cinquain, limerick, haiku, free verse, etc).
2. Distribute handouts for a group project. The group project is to film or act out a version of a ballad poem (such as "Richard Cory" by Edwin Arlington Robinson), complete with script.
3. Assign students to groups.
4. Take questions.
5. Have students begin working. (It may be beneficial to structure it so that some of the individual tasks occur before group work in order to provide scaffolding for the group project.) All projects must be completed by the end of the unit.

Days three-eight: Facilitate learning by walking around room. Start each class period with five minutes of questions/issues. Assess student progress and provide occasional formative assessments. Check in on each student and each group to monitor progress. Collect notecards with questions/interesting facts gleaned from the three videos by the end of the first week. Use the notecards as formative assessments to gauge student understanding of the concepts.

Day nine: Remind students that all work for the unit is due on the following day. Offer a student-led review of key poetry terms and types. This could be a Jeopardy-style game.

Day 10: Short summative assessment (such as a quiz) and presentation of student films/skits. All poetry unit work due.

FUTURE RESEARCH DIRECTIONS

More research is needed in assessing the effectiveness of the flipped method in an ELA classroom, as well as all subject areas. Flipped classrooms across all grade levels would benefit from empirical evidence assessing their effectiveness. While a growing body of research is gathering on the method in STEM classes at the higher education level, dozens of teachers at the secondary level are implementing the method without clear knowledge of its usefulness. In order to keep this from being yet another educational fad, we advocate for research in all disciplines at all grade levels.

A number of researchers are finding that the way the flipped method is implemented varies from teacher to teacher. This is another avenue for research. There seem to be subsets and variations of the flipped method. Some teachers advocate for collaborative work and project-based learning as the key components of the flip, while others use the method along with the same worksheets and activities that they would use in a traditional classroom. In both cases, it would be beneficial to know which *way* of flipping is the best.

CONCLUSION

The flipped method of instruction shows great promise. It has the potential to change the entire paradigm of teaching and cast the teacher, as Baker (2000) envisioned it, as the "guide on the side," rather than the "sage on the stage." However, with any new pedagogical idea, careful research and analysis is needed. We do not believe in abandoning other methods just to implement one. In other words, there is much that is right about current methods of instruction, including teacher-led discussions and hands-on workshop models, particularly in the best practices associated with an ELA curriculum. Perhaps the flipped classroom has a place in project-based learning and inquiry activities, while cohabitating with other, more traditional methods, or perhaps, as the students in our study seemed to imply, the flipped method should only be targeted for specific, perhaps more lower level content knowledge in ELA. Additional research, we believe, is the key to finding the proper balance of the flipped method with other best practices in the ELA classroom.

KEY TERMS AND DEFINITIONS

Advanced Placement English Language and Composition: This course is certified and audited by the College Board. Teachers must submit an audited course plan and receive certification by the College Board in order to teach the AP Lang class. The class is generally taught in the 11th grade and consists of instruction in rhetoric, composition, argumentation, and the analysis of primary sources and non-fiction texts. The course culminates in an annual standardized exam given by the College Board in May.

Flashdrive: This is a small device that stores data and has a Universal Serial Bus (USB) interface. It plugs into the USB port on any standard computer and can upload or download digital content.

Flipped Classroom Method: The process of flipping the traditional instruction paradigm, whereby the lecture or direct instruction is given via video or other digital means and viewed as homework, and the activities normally reserved for homework are completed in class.

Inverted Classroom: Another term for a flipped classroom.

Jing: A computer software program that allows users to record their voices and their actions on a document on their computer screen. Jing is a free download from the Internet and can be accessed from http://www.techsmith.com/jing.html.

Modern Language Association (MLA) Guidelines: These guidelines are formatting rules recommended by the Modern Language Association, a body of members founded in 1883 that oversees the study of language and literature. Most English language arts papers are formatted in adherence to MLA guidelines.

Screen Capture Software: This is the term used for computer software that records the online actions of its users. Users can, for example, highlight, annotate or type text into documents, and screen capture software will record their actions and replay them for other viewers. Screen capture files are saved like document files and can be emailed or pasted into other online venues.

Chapter 33
A Flipped Classroom Design for Preservice Teacher Training in Assessment

Isabelle Nizet
Université de Sherbrooke, Canada

Florian Meyer
Université de Sherbrooke, Canada

ABSTRACT

This chapter presents a strategy for designing a flipped classroom model (Khan, 2011) for the training of future teachers in a university context. This model was designed by a group of university professors with complementary expertise in didactics, learning assessment, and Information and Communication Technologies (ICT) for education. This chapter describes their collective procedure, as well as the chosen design. The approach is based on an instructional systems design method called Méthode d'Ingénierie des Systèmes d'Apprentissage (MISA) (Paquette, 2004). The authors use this framework to describe the different stages of the design process while paying particular attention to the challenges posed by a hybrid model of training in higher education.

INTRODUCTION

For several years now, thanks to the Khan Academy (Khan, 2011), the flipped classroom is a teaching model used in many primary and secondary schools. Teachers see an opportunity to take advantage of technologies (video in particular) that allow students to access concepts and knowledge that are presented by their teacher in the setting of their choice in a personal and timely manner that is adapted to their needs and no longer restricted to school hours. This ensures that students become responsible for listening and watching these presentations in conditions that are likely more conducive to learning (as they are chosen by the students themselves) and that allow them to listen as many times as they feel the need. More important still, this approach ensures that class time usually required for theoretical presentations by the teacher, during which students are often mostly passive and unresponsive, can now be used to place students in active learning situations and

DOI: 10.4018/978-1-4666-8246-7.ch033

to free up the teacher so that he or she can play the valuable roles of pedagogical mediator and coach (Jonnaert & Vanderborght, 2009).

In Quebec, this pedagogical model is being tested in some schools (innovationseducation.org, 2013) but is still very marginal in universities, in particular at the University of Sherbrooke where the experiment we present here takes place. During a course in learning assessment and evaluation, which is mandatory for a Bachelor in Secondary Education where we teach, we realized that the flipped classroom model would be highly suitable to support complex learning concepts and skills related to rubric-referenced assessment.

In this chapter, we begin by presenting the context and background of the project. This includes a description of the practical dimension of professional development for preservice teachers in Quebec, the course in learning assessment and evaluation and the bachelor's program of which this course is a part. Secondly, we describe the theoretical framework supporting our thought process and the development of the project. This includes two important models: the Scholarship of Teaching and Learning model (SoTL) (Kreber, 2002) and the Technological Pedagogical and Content Knowledge model (TPaCK) (Mishra & Koehler, 2006). Thirdly, we describe the collaborative design and implementation process of our flipped classroom project as it relates to the method called *Méthode d'Ingénierie des Systèmes d'Apprentissage* (MISA) (Paquette, 2004). This method identifies four complementary design axes that led us to implement our project and to prepare it for testing with students. Fourthly, taking into account these four different axes, we describe the flipped classroom training environment created for preservice teachers, as well as the different kinds of resources established. Finally, we conclude with an analysis of the collective design process to determine the strengths and weaknesses of the chosen strategy, as well as its relevance in the context of collaborative design. We also include a quick overview of the next steps of the project.

BACKGROUND

The project discussed in this chapter has been initiated at the University of Sherbrooke, a francophone university located in the province of Quebec (eastern Canada). The target students for the flipped classroom are future teachers enrolled in a Bachelor in Secondary Education program, and more particularly those students enrolled in the course in learning assessment.

Bachelor in Secondary Education

The Bachelor in Secondary Education at the University of Sherbrooke[1] is a professional program accredited by the Quebec Ministry of Education, Recreation and Sports (MERS). Upon completion of the program, students receive a teaching certificate that authorizes them to teach in any secondary school in Quebec.

Like all teacher education programs in Quebec, this is a four-year curriculum that consists of a total of 120 credits. In this particular program, these credits are distributed as follows: 24 credits in education, 63 credits in specific disciplines and didactics (some of these courses are taken in partner faculties in conjunction with students pursuing bachelor degrees in these particular disciplines), 21 internship credits including a cyberfolio, and 12 credits for the reflective process, which includes an essay. Five distinct pathways are offered: Mathematics, Science and Technology, French, Social Studies (History, Geography and Citizenship Education), and English as a Second Language (ESL).

The Practical Dimension of Professional Training for Preservice Teachers

The training of future secondary school teachers involves an initial two-credit course in learning evaluation. When offered in a university context, this training has both theoretical and practical dimensions. In a professional program of this nature, the practical dimension is essentially achieved through a long-term process of internships (700 hours of internship over a four-year curriculum); this reinforces the idea that pedagogical courses in the classroom are, comparatively, mostly "theoretical." Although the above mentioned course delivers crucial procedural knowledge to 75 future teachers (year 3) before their third internship, up until this point it is essentially devoted to theory and a few key practical exercises (to improve abilities to design and use rubrics). To avoid the side effects of such a traditional pedagogical model, a complementary laboratory is offered to students in order to promote the implementation of these rubrics within the four core fields covered by this two-credit course-Mathematics, Science and Technology, Social Studies and French. In parallel, students take courses about the didactics of these core fields, which allows them to contextualize rubrics to the content of those fields. After eight weeks, students should begin to design a learning and assessment situation and create a rubric-referenced tool in order to demonstrate their skills for assessing pupils in the classroom. Since research in professional knowledge development shows that future teachers require a space in which they can experience the development of complex know-how, we think that reversing this habit becomes crucial to improve the development of assessment competencies.

Assessment Training: A Pedagogical Challenge

Designing rubrics is an iterative problem-solving approach that requires the development of logical reasoning and the ability to make hypotheses (Scallon, 2004; Mueller, 2009). Also, it is not limited to the application of rules and principles because experimentation and induction (trial and error) play a large role, such that truly structured guidance and contextualized feedback must be provided to students. The creation of pedagogical conditions supporting this type of learning for dozens of teams of students is a true challenge in a two-credit course. The main problem is to increase the supervision of practical rubrics design by the professor and class laboratory tutors. Therefore, we propose to reverse the pedagogical dynamic to free up class time for this purpose, while ensuring that conceptual input is sufficient. The objective is to create, for this portion of the course, conditions that lead to active learning, where future teachers learn by doing while receiving support that is enriched and contextualized to suit various didactic profiles.

FRAMEWORK

Our framework provides the epistemological and theoretical basis underlying our exploratory process: as trainers, we need to ground our pedagogical choices on research results and as researchers; we need to define pedagogical problems. For an epistemological point of view, we refer to the SoTL model (*Scholarship of Teaching and Learning*) (Kreber, 2002). For a theoretical perspective, we refer to the TPACK (*Technological, Pedagogical And Content Knowledge*) model (Mishra & Koehler, 2006).

The SoTL Model: A Systemic and Quality-Oriented Frame for Teaching and Learning

As we monitored training for future teachers, who themselves must develop as reflexive practitioners (Schön, 1983), we decided to adopt the SoTL model as a guide for our own approach to solving pedagogical problems in the classroom. This model suggests that the trainer or teacher is also a researcher who is attempting to fix problems by implementing a research process and reinvesting research results as solutions to problems in a systemic way (see Figure 1). Implementing the SoTL approach means adopting an epistemological posture that places the teacher and students in a professional co-development context that enhances pedagogical knowledge building in a collaborative way. This approach involves four highly intricate questions: What must the students learn? Who are the students and how do they learn? How can their learning process be efficiently supported? How can we know that teaching and learning are effective? This investigation relies on the ability of the teacher to observe and interpret signs of dissatisfaction in both teaching and learning. As a researcher, the teacher's own questions represent the beginning of a research process that helps him or her define local problems, identify specific conceptual choices and design methods to improve the teaching-learning process. Creating knowledge to foster innovation in pedagogy becomes crucial for maintaining teaching and learning quality. Every question can initiate a research process because it can be viewed as the source of the definition of a problem.

In our case, the problem is based on the third question that can be contextualized as follows: How can we support learning of procedural complex knowledge about assessment in a traditional classroom? Following the SoTL model, our questioning must rely on complementary considerations: What will the students learn and what are their learning characteristics? These first two questions of the model require a deeper investigation into learning content and learners' pedagogical needs. Answering the third question requires reflection about alternative pedagogical support and the development of tools that can potentially solve the problem. In this chapter, we answer only the

Figure 1. Scholarship of teaching and learning (SoTL) (Adapted from Bélisle [2012])

first three questions, as our intent is simply to describe the results of the design approach and not the results of the testing of solutions itself. Referring to the SoTL process, we explore the following three questions: What must students learn about assessment techniques? What are their pedagogical needs in a context of procedural learning? How can we support their learning of assessment techniques in a 5-6 hour classroom session?

During our exploration of the third question, we hypothesized that the insertion of a sequence of flipped classrooms in the period devoted to the creation of rubrics could be a relevant pedagogical facilitator to address the above-mentioned issues. In addition, the development of self-study materials helps to free up time for classroom practice related to learning, the underlying assumption being that project materials also promote differentiated pedagogy since access to information about rubrics design is not limited to class time. This open and renewable access is likely to promote co-construction of knowledge because the video sequences will support individual or team learning in accordance with the learning pace of each. These are pedagogical choices that meet the pedagogical needs of students.

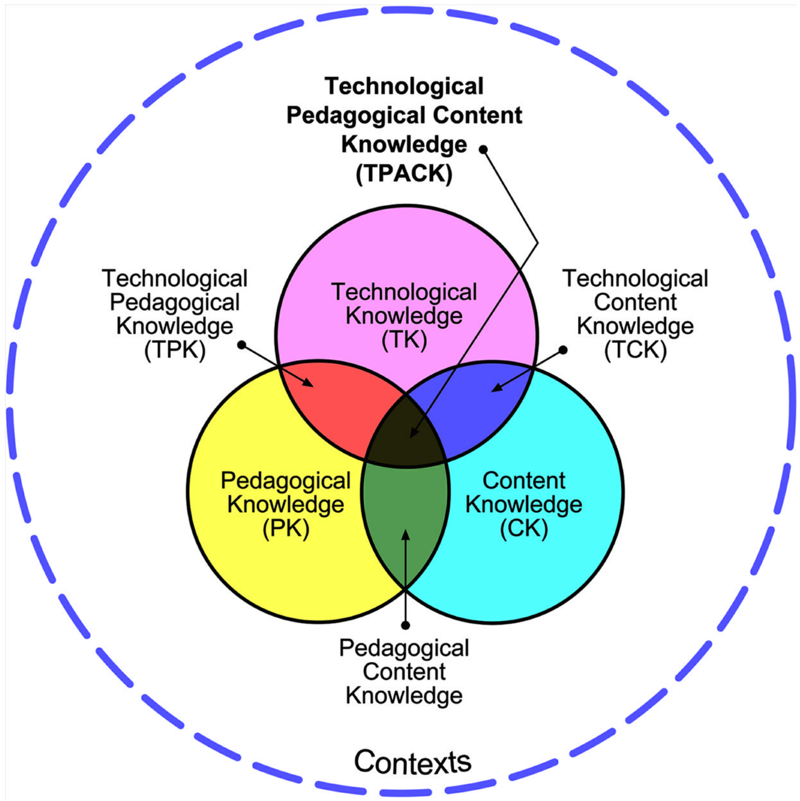
The use of on-line, self-learning videos (combining video, voice and Prezi animations) about the design principles of rubrics would enhance students' practical support in the classroom. The people responsible for supervising the laboratory classes could then act as tutors for the class's professor (team teaching). By doing so, the training model for this course would become a sort of hybrid (Basque, 2005; Charlier, De Schryver & Peraya, 2006), since it would be based on synchronous and asynchronous pedagogical activities. These videos could also be used during training sessions for in-service teachers or as resources that support reflexive thinking during internships for preservice teachers.

The TPACK Model: An Integrative Way of Thinking Shared Expertise

In addition, O'Brien (2008) emphasizes the importance of instructional design and pedagogical signature to explore the SoTL model's third question (Bélisle, 2012). Because we hypothesize that the flipped classroom could meet the needs of our students in terms of learning to create rubrics, we need to define more precisely how we want to implement it. However, before plunging into instructional design using a specific design method (we describe this method in the next section) – since the realization of such a project requires the use of multiple professional knowledge – we must take a step back in this regard in order to understand how to combine our respective knowledge and expertise. Indeed, we are two professors with different knowledge and expertise whose complementarity should be clarified in order to allow us to establish the foundation of an effective collaborative work. Professor Nizet specializes in learning evaluation in high school, while Professor Meyer is a specialist in the integration of ICT in secondary education and distance learning. The TPACK model (Figure 2) appears very helpful to us because it allows us to define our roles in this professional collaboration (Mishra & Koehler, 2006). The reference site Tpack.org defines the model as follows:

At the heart of the TPACK framework, is the complex interplay of three primary forms of knowledge: Content (CK), Pedagogy (PK), and Technology (TK). (…) The TPACK approach goes beyond seeing these three knowledge bases in isolation. TPACK also emphasizes the new kinds of knowledge that lie at the intersections between them, representing four more knowledge bases applicable to teaching with technology: Pedagogical Content Knowledge (PCK), Technological Content Knowledge (TCK), Technological Pedagogical Knowledge (TPK), and the intersection of all three circles, Technological Pedagogical

Figure 2. Technological pedagogical and content knowledge (TPACK) model (Reproduced by permission of the publisher, © 2012 by tpack.org)

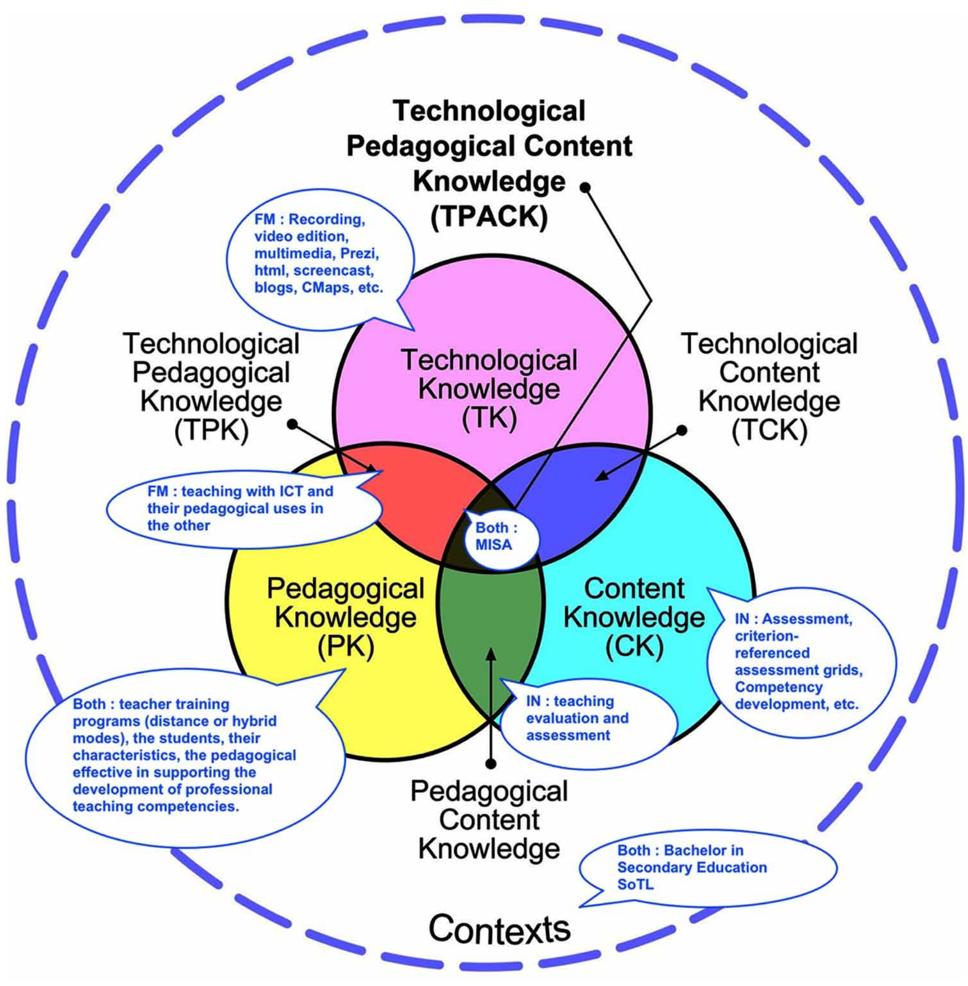


Content Knowledge (TPACK). Effective technology integration for pedagogy around specific subject matter requires developing sensitivity to the dynamic, transactional relationship between these components of knowledge situated in unique contexts. Individual teachers, grade-level, school-specific factors, demographics, culture, and other factors ensure that every situation is unique, and no single combination of content, technology, and pedagogy will apply for every teacher, every course, or every view of teaching (http://tpack.org).

In light of these three forms of knowledge and their interrelations as identified in the TPACK model, the complementarity and compatibility of our expertise and knowledge are easier to identify and characterize, and our collaboration is thus facilitated (Figure 3). Therefore, according to this model, if we wish to realize this flipped classroom project around concepts related to the development of rubrics for evaluating the learning of high school students, it is necessary to use content knowledge (CK) that, in this case, is knowledge about the evaluation of learning. This knowledge is, of course, more the specialty of Professor Nizet and much less that of Professor Meyer. On the other hand, Professor Meyer is rather an expert when it comes to the technological knowledge (TK) necessary to complete the project. In this case, it is a matter of technology-related knowledge that can be exploited in a flipped classroom: recording and video editing, multimedia production tools, concept mapping, webcasting, on-line communication, etc. Finally, we have both developed a solid foundation in the area of pedagogical knowledge (PK), that is to say knowledge about the training of secondary school teachers. In fact, we have both been teaching in preservice teachers training programs (distance or hybrid modes) for many years and have a good knowledge of the students, their characteristics and the pedagogical approaches that we believe effective at supporting the development of professional teaching competencies. We have discovered, however, that our respective pedagogical knowledge is akin to the pedagogical content knowledge (PCK) implemented for teaching evaluation in one case and to the technological pedagogical knowledge implemented for teaching with ICT and their pedagogical uses in the other (TPK).

Needless to say, some explanation and knowledge sharing were necessary for us to understand each other and to define how we could influence and help each other. We quickly observed the complementarity of our knowledge (TPACK) and determined that an instructional systems design method would prove essential for structuring effective sharing and achieving the implementation of our project. We have chosen the instructional systems design method called MISA. It is at the center of what brings us together.

Figure 3. Contextualized technological pedagogical and content knowledge model



METHOD

From a methodological point of view, what we present here is primarily an instructional systems design method because, as we mentioned previously, the purpose of this chapter is to describe the process of designing a flipped classroom session for subsequent insertion in a university course. This project can be considered a case study in a research and development context; the research method itself will be developed during a later phase of this project and will become the subject of another publication.

The MISA Model

Nowadays, various instructional design methods are used and have proven their effectiveness (Ko & Rossen, 2010) at supporting teachers and educators to develop their on-line or in-class courses or educational activities integrating ICT. Inspired by the ADDIE model (Analyze, Design, Develop, Implement and Evaluate), these instructional design methods are structured around a cycle of analysis, design, development and evaluation (Morrison, 2012). Evaluation establishes avenues for the next analysis phase of the cycle. The method we have chosen is called *Méthode d'Ingénierie des Systèmes d'Apprentissage* (MISA) (Paquette, 2004) and it fits perfectly into this cyclical dynamic and offers six phases that are defined as follows:

1. Definition of the project;
2. Preliminary analysis;
3. Definition of the course architecture;
4. Design of the various elements;
5. Implementation and validation; and
6. Diffusion (field implementation) and evaluation.

There are several reasons behind our decision to use this model. First, having been developed in Quebec (Paquette, 2004), this method offers many resources in French that are easier for us to use, as well as numerous illustrations and examples of usage in an educational context that is culturally similar to ours. However, our main motivation for using the MISA model lies in a unique feature that distinguishes it sharply from other methods. Indeed, this method offers the instructional designers that we are an opportunity to reflect, through each of the six stages, upon the four complementary dimensions or axes of design. These four axes are:

1. **DC:** Design of Content (Knowledge and Skill Representation);
2. **DP:** Design of Pedagogical Specifications (Application of Teaching Methods and Approaches);
3. **DM:** Design of Materials (Specification of Learning Materials); and
4. **DD:** Design of Delivery (Delivery Planning).

A model representing the design can be developed for each of these axes. The researchers responsible for this method suggest that designers use typed objects modeling tools (*Modélisation par Objets Typés*: MOT) (Paquette, 2004), but we chose to model our reflections about each of these axes with tables and text.

With regard to the first axis, Design of Content, our content knowledge (CK) (Mishra & Koehler, 2006) has largely been implemented. For us, this was an opportunity to determine the educational goals that this flipped classroom is aiming to reach. In other words, we took advantage of this axis to determine precisely the knowledge that students must construct during this activity, as well as the skills for implementing and exploiting this constructed knowledge. Given our diverse expertise, this first phase of work generated a lot of discussion to clarify our respective understandings.

With regard to the second axis, Design of Pedagogical Specifications, we called upon our respective pedagogical knowledge (PK) complete with its complementary differences, but we also had to construct new knowledge and understanding of the foundations and instructional strategies associated with the flipped classroom model. Our reflections associated with this axis were rich, mostly due to the fact that the flipped classroom model led us to determine how many capsules we should produce and to consider the relevant scripting for each capsule. It also led us to ponder teaching strategies related to the capsules that could be implemented and presented to students while they watch them independently, as well as teaching strategies for use in the classroom that has now been freed from the constraints of the presentation of that learning content. Educational options were therefore increased thanks to the various innovation opportunities offered to us. Finally, this model is strongly influenced by the first axis, but also by the third axis, namely Design of Materials.

With regard to this third axis, it was evident that technological knowledge (TK) was at work. Which technologies could offer possible interesting solutions for the pedagogical strategies chosen? As well, the opportunities afforded by current Web 2.0 technologies led us to imagine that the content capsules could greatly benefit from being multimedia and not just videos. As a result, the teaching screenwriting surrounding the construction of the capsules was strongly influenced. Moreover, in this design axis, we had to take into account the constraints and characteristics of the technological infrastructure of our institution, especially regarding activities during which we ask students to interact, produce or express themselves. In fact, many technological tools were already installed, such as the digital learning environment Moodle, and we were strongly encouraged to use them. As well, open collaborative environments are strongly discouraged for security and data ownership reasons. These aspects are also the main reason that we have spent little energy on the fourth axis, Design of Delivery, as it was more or less imposed on us by default. We have however determined the modalities of publication of the capsules and the timeframes during which all activities would be carried out.

It is also important to mention that an assistant joined our team after the first two phases were completed. She is an experienced secondary school teacher enrolled in one of our university's on-line graduate programs in secondary education. We recruited her precisely because of her technological pedagogical and content knowledge (TPACK) and its relevance to the project. Indeed, our assistant had taken courses related to learning evaluation and ICT integration in secondary education and was familiar with the flipped classroom model. She helped us a great deal during stage four of the MISA model - Design of the various elements - by developing prototypes and refining the models, questioning our different models and refining the various dimensions of the models and their integration.

It is therefore as a team of three educators (two university professors and a secondary school teacher) with complementary knowledge and skills and using a specific instructional design method that we have come to produce a first draft of a flipped classroom about rubric-referenced tools for assessment. To complete our design process, we also consulted the instructional designers specializing in ICT integration from the teachers training support service of our university, as well as our department's didacticians. The following section presents the models produced within each of the four axes.

RESULTS

Given that our design of the flipped classroom session was structured on the four MISA axes, we shall describe the results for all four as each is highly dependent on the others: the design was organized on a systemic pattern in which the output of one phase becomes the input of the next.

In this section, and in accordance with the SoTL approach, we first define the targeted content of learning; this step also corresponds to the Design of Content axis in the MISA model. Learning units were structured based on the content knowledge (CK) expertise of the professor responsible for the course in learning assessment. We then describe the second axis, Design of Pedagogical Specifications, which is based on principles that were collaboratively defined with the team of didactics professors in order to differentiate the approaches with respect to the specificities of each core field (Mathematics, Science and Technology, History, French and Social Studies). Next, we present the results of the third axis, Design of Materials, and describe the choices we made to guide the scripting and technical solutions for content delivery. We then present the principles underlying the Design of Delivery. Finally, we present the Learning Events Net matrix, which is the overall output representing the final planning.

Design of Contents: Knowledge and Skills Representation

Since the first axis of the MISA model refers to the initial question posed by the SoTL approach: "What do the students (have to) learn?" in order to structure pedagogical events that will be described further, we analyzed the learning content as a whole from a cognitive perspective (Anderson, 1993; Tardif, 1992) that identifies declarative, conditional and procedural knowledge. Learning content about assessment is conceptually and technically complex. The students must become familiar with external prescriptions that constrain their practices and with methodological apprenticeship that falls far from their intuitive comprehension of what constitutes assessment in a classroom. To structure content, we identified several clusters of knowledge structured around core concepts or procedures that we refer to here as "sequences." Then, in order to reduce cognitive overload, we divided these sequences into learning units that included both declarative and procedural knowledge in an integrative and progressive way. This content structure will serve as input to the pedagogical and materials design axes.

The self-learning units to be delivered in this flipped classroom project are designed to confer prerequisite knowledge as well as prior declarative knowledge required to begin the first self-learning sequence. This sequence is divided into three short units (units 1 to 3 as shown in Figure 4). It embeds knowledge about assessment of complex tasks (unit 1), a criterion-referenced approach to competencies assessment (unit 2) and professional prescriptions about school report cards (unit 3) previously seen in class during weeks 1 to 6 of the semester. In the province of Quebec, teachers may choose the tools they use to assess students, but they must follow a common framework of pre-determined set of criteria upon which to base their professional judgment. In school report cards, results are now expressed as a score out of 100 and by group average.

The next three learning sequences have different design structures. Self-learning sequence #2 is dedicated to the principles underlying professional judgment (unit 4) and the essential components of *rubrics*: criteria and scoring scales. Students must learn to discriminate between different kinds of appreciation scales (analytical or holistic); they must also become familiar with the advantages and limitations of these instruments and learn to identify their misuse in school contexts. These general principles constitute core complex declarative knowledge for students who have only intuitive knowledge of such tools. In a traditional classroom context, such principles are probably only explained by the teacher orally with the help of some visual aids. In a flipped classroom format, after having been exposed to such information in a self-learning sequence, students will experience a first in-class session dedicated to the analysis of different kinds of rubrics based on scales and criteria such as the ones presented and explained in the self-learning sessions.

After this first in-class session, students will have access to a short, transitive flipped classroom session (self-learning sequence #3) in which

they will have the opportunity to validate their synthesis of core key concepts. This will prepare them to learn about the core procedural knowledge regarding the design of rubrics. In parallel, they will also begin to work on a complex task that will be completed as homework in a team.
